# What Machine Learning is about

<ロト <問ト < 目と < 目と

æ

Problems difficult to address by algorithmic means:

- classification problems spam detection, sentiment analysis, fraudulent transactions, ...
- image recognition
- speech/music recognition
- autoencoding
- data mining (e.g. clustering)

•...

# More and more problems addressed by Machine Learning techniques

イロト イボト イヨト イヨト

## Characteristics

- Iow (metatheoretical) knowledge
- large number of input features
- big volume of training data
- adaptability

Imagenet database: pprox 10 million images

4

イロト イポト イヨト イヨト

## The Machine Learning approach

- define a model for the task to be solved the model depends on a set of parameters Θ
- define a performance metric: some error measure to evaluate the model
- tune the parameters Θ to minimize the error on the training set

(日) (四) (日) (日) (日)

#### Machine learning is an optimization process

Machine Learning problems are in fact **optimization problems**! So, why talking about learning?

• The tuning of parameters is based on observations (training set). We learn from our past experience.

Machine Learning problems are in fact **optimization problems**! So, why talking about learning?

- The tuning of parameters is based on observations (training set). We learn from our past experience.
- the solution to the optimization problem is not given in an analytical form (often there is no closed form solution).
  We use iterative techniques (e.g. gradient descent) to progressively approximate the result, and this can be be understood as a form of learning process.

## Goal: making predictions

Models can also be used to acquire knowledge on input data: finding clusters, making correlations, etc.

8

A D N A B N A B N A B N

## Different types of Learning Tasks

- supervised learning:
  - inputs + outputs (labels)
  - classification
  - regression

- unsupervised learning:
  - just inputs
  - clustering
  - component analysis
  - autoencoding
- reinforcement learning actions and rewards
  - learning long-term gains
  - "model-free" planning

(日)

# Many different techniques

- Different ways to define the models:
  - decision trees
  - mathematical expressions
  - neural networks

- ...

- Different error (loss) functions:
  - mean squared errors
  - logistic loss
  - cross entropy
  - cosine distance
  - maximum margin

- ...

イロト イポト イヨト イヨト

# Features

Any information relative to a datum that describes some of its relevant properties is called a feature.

Features are the input of the learning process.

Learning is highly sensible to the choice of features.

Choosing good features is difficult (requires good domain knowledge).

medical diagnosis	user profiling	weather forecasting
symptoms	demographic data	temperature
patient condition	personal interests	humidity
medical record	social communities	pressure
result of exams	life style	rain, wind,

イロト イロト イヨト イヨト 二日

## Features in image processing

#### Picture taken from the OpenCv python-tutorial

イロト イヨト イヨト イヨト

## Deep learning

**Old approach**: compute by hand good features, and apply a simple and well understood (e.g. linear) learning algorithm.

**Modern (deep) approach**: supply raw data and let to the machine the burden to synthesize good features (internal representations).

Deep learning is implemented through neural networks (NN) A NN is deep when we have multiple hidden layers:

## each hidden layer computes new features from previous ones.

### Relations between research areas

### Image and signal processing:

- OpenCV
- Scipy

individual test (40%)

individual project (60%)

The topic of the project will be given to you (on virtuale) 7-8 days before the scheluded date of the exam, and you need to submit your solution (a single python notebook) within the specified deadline. Typically, you have a week time to complete the task.

The topic is different for each session.

The individual test, once passed, does not need to be repeated.

## Extra credits: MicroRacer

Organize and participate in the MicroRacer annual Championship.

MicroRacer is a small didactic environment for testing DRL techniques in a racing setting, presented at the 8th International Conference on Machine Learning, Optimization, and Data Science. Here is the article.

- random track generation
- fast training (15-30 mn)
- baselines provided
  - 1 point for participating
  - 1 extra point for second place
  - 2 extra points for first place

# **Decision Trees**

イロト イヨト イヨト イヨト 三日

## Function Approximation

Train set: a set of training examples

 $\langle x^{(i)}, y^{(i)} \rangle$ 

where

- $x^{(i)} \in X$  (set of inputs)
- $y^{(i)} \in Y$  (set of outputs)
- i is the instance of the training sample

**Problem**: "learn" the function mapping  $x^{(i)}$  to  $y^{(i)}$ 

Y discrete: classification problem (class prediction) Y continuous: regression problem (value prediction).

Machine learning techniques require a commitment to a given function space H, inside which we look for the function that provides the best approximation for the training set. H reflects the way we are modeling data.

**Example**: Training set =  $\{\langle 2, 3 \rangle, \langle 3, 4 \rangle\}$ 

Machine learning techniques require a commitment to a given function space H, inside which we look for the function that provides the best approximation for the training set. H reflects the way we are modeling data.

**Example**: Training set =  $\{\langle 2, 3 \rangle, \langle 3, 4 \rangle\}$ 

H = linear functions. We have an exact solution: y = x + 1

Machine learning techniques require a commitment to a given function space H, inside which we look for the function that provides the best approximation for the training set. H reflects the way we are modeling data.

**Example**: Training set =  $\{\langle 2, 3 \rangle, \langle 3, 4 \rangle\}$ 

H = linear functions. We have an exact solution: y = x + 1

Adding the instance (1,0), the model is not exact any more.

- we keep the model and content ourselves with approximate answers
- we change the model, for instance taking quadratic functions  $y = -x^2 + 6x 5$

# overfitting the model is too complex and specialized over the peculiarities of the instances of the training set

underfitting the model is too simple and does not allow to express the complexity of the observations.

イロト 不得 トイラト イラト 一日

## Decision trees: an example

A good day to play tennis?

F: Outlook × Humidity × Wind × Temp → Play Tennis?

Every node tests an attribute (feature) X Each branch corresponds to one of the possible discrete values of X Every leaf predicts the answer Y (or a probability P(Y|X))

35

## Learn to build a decision tree

Problem configuration

Input set X

every instance  $x \in X$  is a vector of features of the following kind:

{ Humidity=high, Wind=weak, Outlook=rain, Temp=hot }

► Target function f : X → Y Y takes discrete values (booleans)

• Hypothesis Space  $H = \{h \mid h : X \rightarrow Y\}$  (no restriction)

- we try to model each  $h \in H$  with a decision tree
- each instance x defines a path in the tree leading to a leaf labelled with y

36
## Play-tennis training set

Outlook	Temp	Humidity	Wind	Play
Sunny	Hot	High	Weak	No
Sunny	Hot	High	Strong	No
Overcast	Hot	High	Weak	Yes
Rain	Mild	High	Weak	Yes
Rain	Cool	Normal	Weak	Yes
Rain	Cool	Normal	Strong	No
Overcast	Cool	Normal	Strong	Yes
Sunny	Mild	High	Weak	No
Sunny	Cool	Normal	Weak	Yes

But f is unknown ... so?

イロト イヨト イヨト イヨト 二日

Input and output of the learning task

Input A set of training samples  $\{\langle x^{(i)}, y^{(i)} \rangle\}$  relative to the target function f

Output The hypothesis  $h \in H$  that best approximates f

But f is unknown ... so?

We try to approximate the training set

Let 
$$X = X_1 \times X_2 \cdots \times X_n$$
 where  $X_i = \{\text{True}, \text{False}\}$ 

Can we represent  $Y = X_2 \land X_5$ ? and  $Y = X_4 \lor X_1$ ?

#### Can we represent $Y = X_2 \wedge X_5 \vee (\neg X_3) \wedge X_4 \wedge X_1$ ?

#### Andrea Asperti Università di Bologna - DISI: Dipartimento di Informatica: Scienza e Ingegneria 40

#### Important questions

- do we have a decision tree for each *h* in the space hypothesis?
- if the tree exists, is it unique?
- if it is not unique, do we have a preference?

Main loop:

- 1. assign to the current node the "best" attribute  $X_i$
- 2. create a child node for every possible value of  $X_i$
- for every child node, if all the examples in the training set associated with the node have a same label y, mark the node (leaf) with label y, otherwise iterate from point 1

What is the "best" attribute?

A D N A B N A B N A B N

The entropy H(X) of a random variable X is

$$H(X) = -\sum_{i=1}^{n} P(X = i) \log_2 P(X = i)$$

where n is the number of possible values of X.

Entropy measures the degree of impurity of the information. It is maximal when X is uniformly distributed over all values, and minimal (0) when it is concentrated on a single value.

イロト イボト イヨト イヨト

## Information Theory (Shannon)

Entropy is the average amount of information produced by a stochastic source of data.

*Information* is associated with the *probability* of each data (the "surprise" carried by the event):

- an event with probability 1 carries no information: I(1) = 0
- given two independent events with probabilities p<sub>1</sub> and p<sub>2</sub> their joint probability is p<sub>1</sub>p<sub>2</sub> but the information acquired is the sum of the informations of the two independent events, so

 $I(p_1p_2) = I(p_1) + I(p_2)$ 

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● のへで

It is hence natural to define

$$I(p) = -log(p)$$

Entropy also measures the average number of bits required to transmit outcomes produced by stochastic process X.

Suppose to have n events with the same probability. How many bits do you need to encode each possible outcome?

Entropy also measures the average number of bits required to transmit outcomes produced by stochastic process X.

Suppose to have n events with the same probability. How many bits do you need to encode each possible outcome?

log(n)

Entropy also measures the average number of bits required to transmit outcomes produced by stochastic process X.

Suppose to have *n* events with the same probability. How many bits do you need to encode each possible outcome?

#### log(n)

In this case,

$$H(X) = -\sum_{i=1}^{n} P(X = i) \log_2 P(X = i) \\ = -\sum_{i=1}^{n} 1/n \log_2(1/n) \\ = \log(n)$$

Entropy also measures the average number of bits required to transmit outcomes produced by stochastic process X.

Suppose to have *n* events with the same probability. How many bits do you need to encode each possible outcome?

#### log(n)

In this case,

$$H(X) = -\sum_{i=1}^{n} P(X = i) \log_2 P(X = i) \\ = -\sum_{i=1}^{n} 1/n \log_2(1/n) \\ = \log(n)$$

If events are not equiprobable we can do better!!!

イロト 不得 トイヨト イヨト 二日

#### Information gain

#### Entropy of X

$$H(X) = -\sum_{i=1}^{n} P(X = i) \log_2 P(X = i)$$

Conditional Entropy of X given a specific Y = v

$$H(X|Y = v) = -\sum_{i=1}^{n} P(X = i|Y = v) \log_2 P(X = i|Y = v)$$

#### Conditional Entropy of X given Y

(weighted average over all m possible values of Y)

$$H(X|Y) = \sum_{v=1}^{m} P(Y = v) H(X|Y = v)$$

Information Gain between X and Y:

$$I(X, Y) = H(X) - H(X|Y) = H(Y) - H(Y|X)$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへで

#### Better A or B?

Let us measure the entropy reduction of the target variable Y due to some attribute X, that is the information gain I(Y, X) between Y and X.

$$\begin{split} H(Y) &= -(29/64) \cdot \log_2(29/64) - (35/64) \cdot \log_2(35/64) = .994 \\ H(Y|A = T) &= -(21/26) \cdot \log_2(21/26) - (5/26) \cdot \log_2(5/26) = .706 \\ H(Y|A = F) &= -(8/38) \cdot \log_2(8/38) - (30/38) \cdot \log_2(30/38) = .742 \\ H(Y|A) &= .706 \cdot 26/64 + .742 \cdot 38/64 = .726 \\ I(Y, A) &= H(Y) - H(Y|A) = .994 - .726 = .288 \\ \text{For } B \text{ we get } H(Y|B) = .872 \text{ and } I(Y, B) = .122 \end{split}$$

#### So A is better!

イロト イヨト イヨト イヨト 二日

When attributes are continuous we take decisions based on thresholds:

- we compare thresholds with information gain
- how to choose candidate thresholds?

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

When attributes are continuous we take decisions based on thresholds:

- we compare thresholds with information gain
- how to choose candidate thresholds?
  - sample at discrete intervals
  - order the test set w.r.t. the given attribute and choose thresholds at the average of two consecutive data

#### An example

```
from sklearn import tree
X = [[0,0,0,0], [1,0,0,0], [0,0,0,1], [0,0,1,0], [0,0,1,1],
     [0.1.0.0], [0.1.0.1], [1.1.0.1], [0.1.1.0], [0.1.1.1]]
Y = [0.0.1.1.0.0.1.1.1.0]
#label is 1 if X[2] = X[3]. 0 otherwise
clf = tree.DecisionTreeClassifier(criterion='entropy',
                                  random state=0)
clf = clf.fit(X, Y)
print(clf.predict([1,1,1,1])) #> [1]
print(clf.feature_importances_) #> [0.17, 0.029, 0.4, 0.4]
tree.export_graphviz(clf, out_file='tree.dot')
#dot -T png tree.dot -o tree.png
```

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● のへで

#### Example: the decision tree

In this case, the information gain of individual features is not a good selection policy!

Still, importance is fair, since it is calculated ex post for a single decision tree by the amount that each attribute split point improves the performance measure, weighted by the number of observations the node is responsible for.

≣ 54

# No free lunchInductive Bias

イロト イヨト イヨト イヨト 二日

#### **Problem Configuration**:

- ► a set of instances X every instance x ∈ X is a vector of features (attributes) x = ⟨x<sub>1</sub>, x<sub>2</sub>,...x<sub>n</sub>⟩
- Target function  $f : X \to Y$ , where Y takes discrete values
- Hypothesis Space:  $H = \{h \mid h : X \to Y\}$

**Input (of the training):** A training set of  $\{\langle x^{(i)}, y^{(i)} \rangle\}$  relative to the target function f

**Output (of the training):** The hypothesis  $h \in H$  that better approximate (?!?) the target function f (not known)

7.	13112221		
8.	???		

イロト 不得 トイヨト イヨト

 $2, 3, 5, 9, 17, \dots$ 

Not a single solution. Why one should be better than others?

To learn, we need an inductive bias!

A more complex example: (just for fun) 1. 1 2. 11 3. 21 4. 1211 5. 111221 6. 312211 7. 13112221 8. ???

イロト 不得 トイラト イラト 一日

Exercise: what would a decision tree predict?

Learning can be understood as a search in the Space Hypothesis for the function that better fits the training set (according to some error measure).

**Example**: input described by 20 boolean features; boolean output.

- What is the dimension of the Space Hypothesis?
- How many training instances are need to uniquely determine the target function f?
- If we have m training instances, how many distinct functions satisfy them?
- Given a new instance, how many of the previous ones will satisfy it?

Supposing that all hypothesis have the same probability, there is no reason to prefer one to the other.

#### Hume

Even after the observation of the frequent or constant conjunction of objects, we have no reason to draw any inference concerning any object beyond those of which we have had experience.

The choice of the hypothesis (or model) must be driven by inductive biases, otherwise no learning is possible.

The learning biases are the set of assumptions that the learner uses to predict outputs for new inputs.

イロト 不得 トイヨト イヨト 二日

## An example: Occam's razor

A well known example of inductive bias is the so called Occam's razor:

"The simplest solution consistent with observation is to be preferred" (lex parsimoniae).

Never explicitly stated in Occam's works

Similar concepts expressed by Duns Scoto and Thomas Aquinas:

"Plurality is not to be posited without necessity"

・ロト ・ 母 ト ・ ヨ ト ・ ヨ ト

Occam's razor is e.g. used by decision trees.

## Other examples of inductive biases

- conditional independence if hypothesis are expressed in a Bayesian framework (see later), we assume the conditional independence of the input random variables. Bias used by Naïve Bayes classifiers.
- Maximum margin when drawing a discrimination line between two classes, prefer the one that maximize the width of the margin between elements of the classes. Bias used by Support Vector Machines.
- Features importance compare features (e.g. via information gain) and give priority to the most useful ones. Bias used in Decision Tree learning and several algorithms based on feature selection.
- Nearest neighbours we assume that all data in a small neighbourhood of a given data belongs to a same class. Bias used in k-nearest neighbour algorithm.

The NFL theorem is based on the assumption that any possible extension of the target function beyond the training samples remains equiprobable.

Learning can only be done on a known training dataset. We presume the training set is a significant sample of some target distribution we are trying to learn.

- discriminative approaches try to learn the probability of an output given the input, that is the conditional distribution P(Y|X)
- generative approaches try to learn the joint input-output distribution P(X, Y)

## Overfitting

イロト イヨト イヨト イヨト 二日

## Overfitting

Let us consider the error of the hypothesis h

- on the training set, error<sub>train</sub>(h)
- on the full data set  $\mathcal{D}$ ,  $error_{\mathcal{D}}(h)$

We say that h overfits the training set if there exists another hypothesis h' such that

 $error_{train}(h) < error_{train}(h')$ 

but

 $error_{\mathcal{D}}(h) > error_{\mathcal{D}}(h')$ 

69

## Overfitting and model complexity

Problem: we do not know  $\mathcal{D}!$ 

Divide the available data in two disjoint sets: training set to be used to choose a candidate hvalidation set to be used to asses the accuracy of h

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

- early stopping: terminate the construction of the tree as soon as the classification improvement is not statistically significative (e.g. the information gain is below some threshold, and/or we do not have sufficient data)
- post-pruning: develop the full tree and then proceed to backward prune it

イロト イヨト イヨト イヨト 二日
Build a full and exact decision tree for the training set.

Repeat the following operation until further pruning do not improve accuracy:

- 1. for any subtree, compute the impact of its removal on the classification accuracy on the validation set
- 2. greedily perform pruning of the subtree that optimizes accuracy

(日)

# Variants: Gini's impurity

Gini's impurity measures the probability that a generic element get misclassified according to the current classification (an alternative to entropy).

Given *m* categories, let  $f_i$  be the fraction of data with label *i*. This is equal to the probability that an input belongs to the category *i*. The probability of misclassifying it is hence  $1 - f_i$ , and its weighted average on all categories is just Gini's impurity, that is

$$I_G(f) = \sum_{i=1}^m f_i(1-f_i) = \sum_{i=1}^m (f_i - f_i^2) = \sum_{i=1}^m f_i - \sum_{i=1}^m f_i^2 = 1 - \sum_{i=1}^m f_i^2$$

This metric is applied to every child node, and values are summed in a weighted way (similarly to the definition of Information-gain) to get a measure of the quality of an attribute.

74

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

#### Better A or B?

Let us evaluate the split using Gini's impurity.

For the attribute *A*:  $I_G(A = T) = 1 - (21/26)^2 - (5/26)^2 = .310$   $I_G(A = F) = 1 - (8/38)^2 - (30/38)^2 = .332$  $I_G(A) = .310 \cdot 26/64 + .332 \cdot 38/64 = .323$ 

For the attribute *B*:  $I_G(B = T) = 1 - (18/51)^2 - (33/51)^2 = .456$   $I_G(B = F) = 1 - (11/13)^2 - (2/13)^2 = .260$  $I_G(B) = .456 \cdot 51/64 + .260 \cdot 13/64 = .416$ 

#### Hence, A is better (lower impurity)

イロト イポト イヨト イヨト

- easy to understand: simple logical rules, trees can be visualized
- little or no data preprocessing is required
- very low prediction cost
- can be used with both discrete and continuous features

イロト 不得 トイラト イラト 一日

- high risk of overfitting
- selection of attributes quite unstable
- easy to build strongly unbalanced trees, especially if a class is dominant It can be useful to pre-balance the dataset.

イロト 不得 トイラト イラト 一日

>>> X = [[0,0],[1,1]]
>>> Y [[0,1]]
>>> clf = tree.DecisionTreeClassifier()
>>> clf = clf.fit(X,Y)
```

- > any method in the first part of course can be tested that easily
- you are warmly invited to play with them
- do not be too naif in your project

イロト イヨト イヨト イヨト 三日

Decision Trees are normally used as components in Random Forests, operating as an ensemble.

Ensemble techniques exploits the principle that a large number of relatively uncorrelated models (e.g. trees) operating as a committee will typically outperform any of the individual constituent models.

#### Ensure differentiation by:

- Bagging: feeding different, randomly choosen sets of input data
- Feature Randomness: building trees from random subsets of features

#### Approximation problem:

- Features X, labels (categories) Y
- Training set  $\{\langle x^{(i)}, y^{(i)} \rangle\}$
- Hypothesis Space  $H = \{h \mid h : X \to Y\}$

#### Learning = search/optimization in H

- Different objectives are possible
  - minimize the error on the training set (0-1 loss)
  - among candidate solutions look for the "simpler" one (occam razor's)
- No learning is possible without an inductive bias (NFL theorem)

# **Probability basics**

イロト イヨト イヨト イヨト 二日

# Probability basics

#### Events

- discrete and continuous random variable

#### Axioms of Probability Theory

- a reasonable theory of uncertainty
- Independent events
- Conditional Probability
- Bayes Rule
- Joint Probability Distribution
- Expectation
- Independence, conditional Independence

A random variable X denotes an outcome about which we are uncertain, for instance the result of a randomized experiment

#### Examples

- X = true if a (randomly drawn) student in this room is male
- X = first name of the student
- X = true if two randomly drawn students in this room have the same birthday

We define P(X) (probability of X) as the fraction of times X is true, in repeated runs of the same experiment.

# More formally

- the set Ω of possible outcomes of a random experiment is called sample space
  - e.g. the set of students in this room
- a random variable is a measurable function over  $\Omega$ :
  - discrete: e.g. gender:  $\Omega \to \{m, f\}$
  - continuous: e.g. height:  $\Omega \to \mathcal{R}$
- an event is an arbitrary subset of Ω

- 
$$\{x \in \Omega | gender(x) = m\}$$

- $\{x \in \Omega | height(x) \leq 175cm\}$
- we are interested in probabilities of specific events
  - P(gender = m)
- and in their probabilities conditioned on other events
  - $P(gender = m | height \leq 175)$

The definition of the sample space requires some caution.

Our probability intuition relies on the assumption that all samples in the space have the same probability.

**Example**: toss of a pair of dices. The outcome is an integer number between 2 and 12. However, not all of them have the same probability.

イロト 不得 トイヨト イヨト 二日

Better to consider the pairs of outcomes of each dice as elements of the sample space, and a random variable X expressing their sum.

# Graphical Visualization

The probability P(A) of the event A is the ratio between the area of A and the area of the full sample space.

イロト イヨト イヨト イヨト

# **Probability Axioms**

87

$$P(\neg A) = 1 - P(A)$$

**Proof:** We know that

$$P(A \lor B) = P(A) + P(B) - P(A \land B)$$

and in particular

$$P(A \lor \neg A) = P(A) + P(\neg A) - P(A \land \neg A)$$

but

$$P(A \lor \neg A) = P(True) = 1$$
 and  $P(A \land \neg A) = P(False) = 0$ 

so

$$1 = P(A) + P(\neg A) - 0$$

q.e.d.

88

Another interesting theorem

$$P(A) = P(A \wedge B) + P(A \wedge \neg B)$$

**Proof:** We know that

$$P(A \lor B) = P(A) + P(B) - P(A \land B)$$

Since

$$A = A \land (B \lor \neg B) = (A \land B) \lor (A \land \neg B)$$

we have:

$$P(A) = P(A \land B) + P(A \land \neg B) - P((A \land B) \land (A \land \neg B))$$
  
=  $P(A \land B) + P(A \land \neg B) - P(False)$   
=  $P(A \land B) + P(A \land \neg B)$ 

イロト イロト イヨト イヨト 二日

A is a k-valued discrete random variable if it may take exactly one of the values in the set  $\{\nu_1, \nu_2, \dots, \nu_k\}$ .

 $P(A = \nu_i)$  is the event of all samples where A takes value  $\nu_i$ .

$$P(A = \nu_i \land A = \nu_j) = 0 \text{ if } i \neq j$$
  

$$P(A = \nu_1 \lor A = \nu_2 \lor \dots A = \nu_k) = 1$$

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● のへで

# Conditional Probability

**Definition** The conditional probability of the event A given the event B is defined as the quantity

$$P(A|B) = rac{P(A \wedge B)}{P(B)}$$

Corollary: Chain rule

$$P(A \land B) = P(B) \cdot P(A|B) = P(A) \cdot P(B|A)$$

イロト 不得 トイラト イラト 一日

Two events A and B are independent when

P(A|B) = P(A)

That is, the event B has no influence over A. As a corollary,

$$P(A \wedge B) = P(A) \cdot P(B)$$

Moreover, since

$$P(A \wedge B) = P(B|A) \cdot P(A)$$

we also have

$$P(B|A) = P(B)$$

イロト イヨト イヨト イヨト 二日

Two "orthogonal" events:

イロト イロト イヨト イヨト 二日

$$P(A|B) = \frac{P(A) \cdot P(B|A)}{P(B)}$$

#### Example

- ▶ in a school 60% of students are boys and 40% are girls.
- girls wear in the same number skirts and trousers
- boys only wear trousers

If we see a student wearing trousers, what is the probability that is a girl?

The probability a priori that a student is a girl is

P(G) = 2/5

the probability that a student wears trousers is

P(T) = 1/5 + 3/5 = 4/5

the probability that a student wear trousers, given that the student is a girl, is

P(T|G) = 1/2

Hence, the probability that a student wearing trousers is a girl is

$$P(G|T) = \frac{P(G) \cdot P(T|G)}{P(T)} = \frac{2/5 \cdot 1/2}{4/5} = 1/4$$

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● のへで

#### Another formulation of Bayes rule

$$P(Y|X) = \frac{P(Y) \cdot P(X|Y)}{P(X)}$$

or more precisely, for every i, j,

$$P(Y = y_i | X = x_j) = \frac{P(Y = y_i) \cdot P(X = x_j | Y = y_i)}{P(X = x_j)}$$

But we know that

$$P(X = x_j) = \sum_i P(X = x_j, Y = y_i) = \sum_i P(Y = y_i) \cdot P(X = x_j | Y = y_i)$$

so

$$P(Y = y_i | X = x_j) = \frac{P(Y = y_i) \cdot P(X = x_j | Y = y_i)}{\sum_i P(Y = y_i) \cdot P(X = x_j | Y = y_i)}$$

96

# Posterior, likelihood, prior and marginal

"Marginal" because we marginalized (i.e. integrated) over Y

• • • • • • • • • • • •

# The Joint Distribution Bayes classifiers Naïve Bayes

イロト イポト イヨト イヨト

э

1. build a table with all possible combinations of values of random variables (features)

2. compute the probability for any different combination of values

gender	working	health	prob
	hours		(params)
F	≤ 40	poor	0.25
F	$\leq$ 40	rich	0.03
F	> 40	poor	0.04
F	> 40	rich	0.01
М	$\leq$ 40	poor	0.33
М	$\leq$ 40	rich	0.10
М	> 40	poor	0.13
М	> 40	rich	0.11

Given *n* (boolean) features, we need to compute  $2^n - 1$  parameters.

99

Having the joint distribution we may compute the probability of any event expressible as a logical combination of the features

$$P(E) = \sum_{row \in E} P(row)$$

# Example

Let us compute the probability P(M, poor)

gender	w. hours	wealth	prob.
F	$\leq$ 40	poor	0.25
F	$\leq$ 40	rich	0.03
F	> 40	poor	0.04
F	> 40	rich	0.01
М	<u>≤</u> 40	poor	0.33
М	$\leq$ 40	rich	0.10
М	> 40	poor	0.13
М	> 40	rich	0.11

P(M, poor) = 0.33 + 0.13 = 0.46

It is also easy to compute the probability of an event  ${\it E}_1$  given another event  ${\it E}_2$ 

$$P(E_1|E_2) = \frac{P(E_1 \wedge E_2)}{P(E_2)} = \frac{\sum_{row \in E_1 \wedge E_2} P(row)}{\sum_{row \in E_2} P(row)}$$

イロト イヨト イヨト イヨト 三日

$$P(M|poor) = rac{P(M, poor)}{P(poor)}$$

We know that P(M, poor) = 0.46. Let us compute P(poor):

gender	w. hours.	wealth	prob.
F	≤ <b>4</b> 0	poor	0.25
F	$\leq$ 40	rich	0.03
F	> 40	poor	0.04
F	> 40	rich	0.01
М	≤ <b>4</b> 0	poor	0.33
М	$\leq$ 40	rich	0.10
М	> 40	poor	0.13
М	> 40	rich	0.11

P(poor) = .75 and P(M|poor) = 0.46/0.75 = 0.61

イロト イヨト イヨト イヨト 三日

Conditional Probability vs. learning

Instead of computing

 $f: X \to Y$ 

we may compute the probability

p: P(Y|X)

We know that we can use the joint distribution, so we just need to compute it.

# End of the story?

# Complexity issues

Let us build the joint table relative to

 $P(Y = wealth | X_1 = gender, X_2 = orelav.)$ 

$X_1 = \text{gender}$	$X_2 = $ ore lav.	$P(rich X_1, X_2)$	$P(poor X_1, X_2)$
F	$\leq$ 40	.09	.91
F	> 40	.21	.79
М	$\leq$ 40	.23	.77
М	> 40	.38	.62

To fill the table we need to compute  $4 = 2^2$  parameters.

If we have *n* random variable  $X = X_1 \times X_2, ..., X_n$  where each  $X_i$  is boolean, we need to compute  $2^n$  parameters.

These parameters are probabilities: to get reasonable value we would need a huge amount of data.

We know that

$$P(Y = y_i | X = x_j) = \frac{P(Y = y_i) \cdot P(X = x_j | Y = y_i)}{\sum_i P(Y = y_i) \cdot P(X = x_j | Y = y_i)}$$

So, to compute  $P(Y = y_i | X = x_j)$  it is enough to compute

$$P(Y)$$
 and  $P(X_1, X_2, \dots, X_n | Y)$ 

• how many parameters for P(Y)?

• how many parameters for 
$$P(X_1, X_2, \dots, X_n | Y)$$
?

#### Naïve Bayes assumes that

$$P(X_1, X_2, \ldots, X_n | Y) = \prod_i P(X_i | Y)$$

that is, given Y,  $X_i$  and  $X_j$  are independent from each other.

イロト イヨト イヨト イヨト 三日

#### Two events $X_i$ and $X_j$ are independent given Y if

 $P(X_i|X_j, Y) = P(X_i|Y)$ 

**Example 1** A box contains two coins: a regular coin and a fake two-headed coin (P(H)=1). Choose a coin at random, toss it twice and consider the following events:

- A = First coin toss is H
- B = Second coin toss is H
- $\mathsf{C}=\mathsf{First}\ \mathsf{coin}\ \mathsf{is}\ \mathsf{regular}$

A and B are NOT independent (prove it), but they are conditionally independent given C.

**Example 2** For individuals, height and vocabulary are not independent, but they are if age is given.

(日)
Conditional independence in Naïve Bayes

$$P(X_1, X_2|Y) = P(X_1|X_2, Y) \cdot P(X_2|Y)$$
by the chain rule  
=  $P(X_1|Y) \cdot P(X_2|Y)$ by cond. ind.

In general,

$$P(X_1, X_2, \dots, X_n | Y) = \prod_i P(X_i | Y)$$

How many parameters to describe  $P(X_1, X_2, ..., X_n | Y)$  (in the boolean case)?

without conditional Independence

in Naïve Bayes

イロト イヨト イヨト イヨト 三日

### Naïve Bayes in a nutshell

### Bayes rule

$$P(Y = y_i | X_1, \dots, X_n) = \frac{P(Y = y_i) \cdot P(X_1, \dots, X_n | Y = y_i)}{P(X_1, \dots, X_n)}$$

#### Naïve Bayes

$$P(Y = y_i | X_1, \dots, X_n) = \frac{P(Y = y_i) \cdot \prod_j P(X_j | Y = y_i)}{P(X_1, \dots, X_n)}$$

Classification of a new sample  $x^{new} = \langle x_1, \dots x_n \rangle$ 

$$Y^{new} = \arg \max_{y_i} P(Y = y_i) \cdot \prod_j P(X_j = x_j | Y = y_i)$$

### Learning algorithm

Discrete Random variables  $X_i, Y$ 

### Training

• for any possible value  $y_k$  of Y, estimate

$$\pi_k = P(Y = y_k)$$

for any possible value x<sub>ij</sub> of X<sub>i</sub> estimate

$$\theta_{ijk} = P(X_i = x_{ij} | Y = y_k)$$

• Classification of  $a^{new} = \langle a_1, \dots a_n \rangle$ 

 $Y^{new} = \arg \max_{y_k} P(Y = y_k) \cdot \prod_i P(X_i = a_i | Y = y_k)$ = arg max<sub>k</sub>  $\pi_k \cdot \prod_i \theta_{ijk}$ 

supposing that  $a_i = x_{ij}$  (i.e.  $a_i$  is the *j*-th among the discrete values of the attribute  $X_i$ )

### Prediction

New instance:

 ${\small Outlook} = {\small Sunny}, {\small Temp}. = {\small Cool}, {\small Humidity} = {\small High}, {\small Wind} = {\small Strong}$ 

We need to compute

 $arg max_{y \in yes, no} p(y) \cdot p(sunny|y) \cdot p(cool|y) \cdot p(high|y) \cdot (strong|y)$ 

that is, we need to compare

$$\pi_{\text{yes}} \cdot \theta_{\text{sunny,yes}} \cdot \theta_{\text{cool,yes}} \cdot \theta_{\text{high,yes}} \cdot \theta_{\text{strong,yes}} \\= 9/14 \cdot 2/9 \cdot 3/9 \cdot 3/9 \cdot 3/9 = .0053$$

$$\pi_{no} \cdot \theta_{sunny,no} \cdot \theta_{cool,no} \cdot \theta_{high,no} \cdot \theta_{strong,no}$$
  
= 5/14 \cdot 3/5 \cdot 1/5 \cdot 4/5 \cdot 3/5 = .0205

### NO!

# Generative techniquesLimitations and cautions

### The generative nature of Naive Bayes

We are interested in computing

 $P(Y = y_i | X_1, \ldots, X_n)$ 

Bayes' rule allow to reverse the problem, asking instead to understand the **distribution of data**, given the category

 $P(X_1,\ldots,X_n|Y=y_i)$ 

▲□▶ ▲圖▶ ▲ 臣▶ ▲ 臣▶ 三臣 - のへの

### Classification of new data

We classify a new data point by asking to which one of the input distributions it is the most likely to belong to:

The distributions we would be interested in are the joint distributions

 $P(X_1,\ldots,X_n|Y=y_i)$ 

In the case of mnist, the distributions of images, reparted by categories, in a space with 784 dimensions.

Since this is unfeasible, we use the naive approach to assume that all features are independent, reducing the problem to the estimation of

 $P(X_j|Y=y_i)$ 

for all possible feautures  $j = 1, \ldots, n$ .

In some cases, MLE for  $P(X_i|Y)$  may be 0 e.g. P(Play = No|Outlook = Overcast)

Why should be worry?

How can we avoid the problem?

## Naïve Bayes assumes events are independent from each other (given Y).

### What if this is not the case?

イロト 不得 トイラト イラト 一日

### Limitations

Suppose we have a set of random images, with pixels either 0 or 1.

Choose two pixels  $p_1$  and  $p_2$ . We want to classify the image in category A if  $p_1 == p_2$  and in category B otherwise.

It looks like a pretty simple classification. Let us try to use Naive Bayes.

```
What is P(p_1 = 1|A)?
What is P(p_1 = 1|B)?
What is P(p_2 = 1|A)?
What is P(p_2 = 1|A)?
```

### So? ...

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● のへで

### About Maximum Likelihood Estimation

イロト イヨト イヨト イヨト 三日

### Back to parameters estimation

### Maximum likelihood estimates (MLE's):

$$\pi_k = P(Y = y_k) = \frac{\#\mathcal{D}\{Y = y_k\}}{|\mathcal{D}|}$$

$$heta_{ijk} = P(X_i = x_{ij} | Y = y_k) = rac{\# \mathcal{D}\{X_i = x_{i,j} \land Y = y_k\}}{\# \mathcal{D}\{Y = y_k\}}$$

Andrea Asperti Università di Bologna - DISI: Dipartimento di Informatica: Scienza e Ingegneria 125

### Back to parameters estimation

### Maximum likelihood estimates (MLE's):

$$\pi_k = P(Y = y_k) = \frac{\# \mathcal{D}\{Y = y_k\}}{|\mathcal{D}|}$$

$$\theta_{ijk} = P(X_i = x_{ij} | Y = y_k) = \frac{\# \mathcal{D}\{X_i = x_{i,j} \land Y = y_k\}}{\# \mathcal{D}\{Y = y_k\}}$$

### Why?

Suppose to toss a (possibly fake) coin 10 times. We get 6 Heads (H) and 4 Tails (T).

イロト イヨト イヨト イヨト 三日

One could "naturally" conclude that P(H) = .6 and P(T) = .4.

Suppose to toss a (possibly fake) coin 10 times. We get 6 Heads (H) and 4 Tails (T).

One could "naturally" conclude that P(H) = .6 and P(T) = .4.

Suppose that there are just two possibilities:

- the coin is fair, that is P(H) = .5 and P(T) = .5
- the coin is fake, with probabilities P(H) = .7 and P(T) = .3

Which is the most likely according to our observations, and why?

### Bernoulli's Distribution (ex. flipping a coin)

two possible outcomes 0 and 1 with probabilities  $\theta$  and  $1 - \theta$ .

Let  $X^n$  be the number of 0 in a sequence of n flips  $X^n$  follows a binomial distribution

$$P(X^n = \alpha_0 | \theta) = \binom{n}{\alpha_0} \cdot \theta^{\alpha_0} \cdot (1 - \theta)^{\alpha_1}$$

where  $\alpha_1 = n - \alpha_0$  is the number of 1 in the sequence (id est,  $\alpha_0 + \alpha_1 = n$ )

 ・
 ・
 ・
 ・
 ・
 ・
 ・
 ・
 ・
 ・

### Back to our example

$$n = 10, \ \alpha_0 = 6 \text{ and } \alpha_1 = 4.$$
  
If  $\Theta = .5 \text{ and } 1 - \Theta = .5$ 
$$P(X^n = 6|\theta) = {n \choose \alpha_0} \cdot \theta^{\alpha_0} \cdot (1 - \theta)^{\alpha_1} = {10 \choose 6} \cdot \left(\frac{1}{2}\right)^6 \cdot \left(\frac{1}{2}\right)^4 = .205$$

If 
$$\Theta = .7$$
 and  $1 - \Theta = .3$ 

$$P(X^n = 6|\theta) = \binom{n}{\alpha_0} \cdot \theta^{\alpha_0} \cdot (1-\theta)^{\alpha_1} = \binom{10}{6} \cdot \left(\frac{7}{10}\right)^6 \cdot \left(\frac{3}{10}\right)^4 = .200$$

So,  $\Theta = .5$  is slightly more likely than  $\Theta = .7$ .

#### What is the most likely value for $\Theta$ ?

イロト イヨト イヨト イヨト 三日

$$\hat{ heta} = rg \max_{ heta} P(X^n = lpha_0 | heta) = \ = rg \max_{ heta} heta^{lpha_0} \cdot (1 - heta)^{lpha_1}$$

Equivalently we may look for  $\boldsymbol{\theta}$  maximizing the logarithm of the previous expression

$$\ln(\theta^{\alpha_0} \cdot (1-\theta)^{\alpha_1}) = \alpha_0 \ln(\theta) + \alpha_1 \ln(1-\theta)$$

Deriving with respect to  $\boldsymbol{\theta}$  we get

$$\frac{\alpha_0}{\theta} - \frac{\alpha_1}{1-\theta} = \frac{\alpha_0 - \alpha_0 \theta - \alpha_1 \theta}{\theta \cdot (1-\theta)}$$

That is zero for

$$\theta = \frac{\alpha_0}{\alpha_0 + \alpha_1} = \frac{\alpha_0}{n}$$

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● のへで

**Discrete Distribution** (ex. tossing a dice) k possible outcomes  $\{1, 2, ..., k\}$  with probabilities  $\theta_i$  where  $\sum_i \theta_i = 1$ .

Sequence of *n* tosses: multinomial distribution

$$P(X^n = \overline{\alpha_i} | \theta) = c_{\overline{\alpha_i}} \prod_i \theta_i^{\alpha_i}$$

where  $\alpha_i$  is the number of *i* in the sequence and  $c_{\overline{\alpha_i}}$  is a combinatorial constant not depending on  $\theta$ 

**MLE**: 
$$\theta_i = \frac{\alpha_i}{\sum_i \alpha_i} = \frac{\alpha_i}{n}$$

# Document classification (bag of words approach)

A D N A B N A B N A B N

event  $X_i$  = i-th word in the document: a discrete random variable assuming as many values as words in the language

$$\theta_{i,word,\ell} = P(X_i = word | Y = \ell)$$

probability that in a document of the category " $\ell$ " the word "word" appears at position "i"

we assume that all event are independents (?) and have a distribution independent from the position (?)

$$\theta_{i, word, \ell} = \theta_{j, word, \ell} = \theta_{word, \ell}$$

### Training and classification

Discrete random variables  $X_i, Y$ 

### Training

• for any possible value  $y_k$  of Y, estimate

$$\pi_k = P(Y = y_k)$$

• for any possible value  $x_{ij}$  of the attribute  $X_i$  estimate

$$\theta_{ijk} = P(X_i = x_{ij} | Y = y_k)$$

• Classification of  $a^{new} = \langle a_1, \ldots a_n \rangle$  (sequence of words)

 $Y^{new} = \arg \max_{y_k} P(Y = y_k) \cdot \prod_i P(X_i = a_i | Y = y_k)$ = arg max<sub>k</sub>  $\pi_k \cdot \prod_i \theta_{ijk}$

where  $x_{ij} = a_i$ 

### Maximum likelihood estimates (MLE's):

 $\blacktriangleright \pi_k = P(Y = y_k)$ 

fraction of the documents in category  $y_k$ 

•  $\theta_{i,word,k} = \theta_{word,k} = P(X = word | Y = y_k)$ frequency of the word "word" in documents of the category  $y_k$ 

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● のへで

### Log likelihood

### Instead of

$$Y^{new} = \arg \max_{y_k} P(Y = y_k) \cdot \prod_i P(X_i = w_j | Y = y_k)$$
  
= arg max<sub>k</sub>  $\pi_i \cdot \prod_i \theta_{ijk}$ 

We may compute

$$\begin{array}{l} Y^{new} = \arg \; \max_{y_k} \; \log(P(Y = y_k) \cdot \prod_i P(X_i = w_j | Y = y_k)) \\ = \arg \; \max_k \; \log(\pi_k) + \sum_i \log(\theta_{ijk}) \end{array}$$

Moreover, if  $\theta_{ijk} = \theta_{i'jk} = \theta_{jk}$ 

$$\sum_{i} \log(\theta_{ijk}) = \sum_{j} n_j \cdot \log(\theta_{jk})$$

where  $n_j$  is the number of occurrences of the word  $w_j$  in the document to be classified.

イロト イヨト イヨト イヨト 三日

### Cosine similarity

Consider vectors where each word is a different dimension.

### Training

For any category k build a "spectral" vector

 $s_k = \langle log( heta_{jk}) 
angle_{j \in words}$ 

 $\theta_{jk}$  = frequency of the word j in documents of the category k.

Given a new document, compute a vector

 $d = \langle \textit{n}_j \rangle_{j \in \textit{words}}$ 

and classify the document as

### Geometric definition

 $\mathbf{a} \cdot \mathbf{b} = |\mathbf{a}| |\mathbf{b}| \cos(\theta)$ 

where  $\boldsymbol{\theta}$  is the angle between the two vectors

#### Analytic definition

given  $a = (a_1, a_2, ..., a_n)$ and  $b = (b_1, b_2, ..., b_n)$ 

$$\mathbf{a} \cdot \mathbf{b} = \sum_{i=1}^n a_i b_i$$

イロト 不得 トイヨト イヨト 二日

### Equivalence

By the cosine rule (a generalization of Pythagoras' theorem),

$$|\mathbf{a} - \mathbf{b}|^2 = |\mathbf{a}|^2 + |\mathbf{b}|^2 - 2|\mathbf{a}||\mathbf{b}|\cos(\theta)$$

$$\mathbf{a} \cdot \mathbf{b} = \frac{|\mathbf{a}|^2 + |\mathbf{b}|^2 - |\mathbf{a} - \mathbf{b}|^2}{2}$$

Analytically (planar case):  
let 
$$\mathbf{a} = [a_1, a_2]$$
 and  $\mathbf{b} = [b_1, b_2]$ ; we get  
 $\mathbf{a} \cdot \mathbf{b} = \frac{a_1^2 + a_2^2 + b_1^2 + b_2^2 - (a_1 - b_1)^2 - (a_2 - b_2)^2}{2} = a_1b_1 + a_2b_2$ 

### The linear nature of Naïve Bayes (boolean case)

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

### The linear nature of Naïve Bayes

### $X_i, Y$ booleans

Classification of  $\vec{x} = \langle x_1, \ldots, x_n \rangle$ :

$$\frac{P(Y=1|X_1...X_n=\vec{x})}{P(Y=0|X_1...X_n=\vec{x})} = \frac{P(Y=1)\prod_i P(X_i=x_i|Y=1)}{P(Y=0)\prod_i P(X_i=x_i|Y=0)} \ge 1$$

Passing to logarithms

$$log rac{P(Y=1)}{P(Y=0)} + \sum_{i} log rac{P(X_{i}=x_{i}|Y=1)}{P(X_{i}=x_{i}|Y=0)} \geq 0$$

Let  $\theta_{ik} = P(X_i = 1 | y = k)$  (hence  $P(X_i = 0 | y = k) = 1 - \theta_{ik}$ ), then we have the following linear discrimination test:

$$\log \frac{P(Y=1)}{P(Y=0)} + \sum_{i} x_{i} \cdot \log \frac{\theta_{i1}}{\theta_{i0}} + \sum_{i} (1-x_{i}) \cdot \log \frac{1-\theta_{i1}}{1-\theta_{i0}} \ge 0$$

### The case unfolding trick

Consider a function f(x) where x is a boolean variable, then:

$$f(x) = x * f(1) + (1 - x) * f(0)$$

In general, given a function f(x) with x ranging over a discrete domain  $\{a_1, \ldots, a_n\}$  we can unfold f in the form

$$f(x) = \text{case } x \text{ of:}$$

$$[a_1 \Rightarrow f(a_1) \\ |a_2 \Rightarrow f(a_2) \\ \dots \\ |a_n \Rightarrow f(a_n) \\ ]$$

A form of (finite) memoization.

イロト イヨト イヨト イヨト 三日

Classification algorithms based on a linear combination of the features values.

Every feature is evaluated independently from the others and contributes to the result in a linear way, with a suitable weight (that is a parameter of the model, to be estimated).

For instance, if the features are pixels of some image, we may use linear methods only up some normalization (in position and dimension) of the object to be recognized.

(日)
## Gaussian Naïve Bayes

イロト イヨト イヨト イヨト 二日

For instance,  $X_i$  could be the height or age or annual income of some individual, or the color of a pixel in an image, etc.

To use Naïve Bayes we need to compute  $P(X_i|Y)$ , but if  $X_i$  is continuous, pointwise probabilities are null.

A common approach is to suppose  $P(X_i|Y)$  has a Gaussian (or Normal) distribution.

#### Gaussian Distribution

Probability density (with integral = 1)

$$p(x|\mu,\sigma) = \frac{1}{\sigma\sqrt{2\pi}}e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

イロト イロト イヨト イヨト 二日

#### Example

Classify gender given height.

イロト イヨト イヨト イヨト

э

#### Accuracy, Precision and Recall

#### Descriptive parameters of the model

We assume (inductive bias) that for every value  $y_k$  of Y the random variable  $P(X_i|Y = y_k)$  has a Gaussian distribution

$$N(x|\mu_{ik},\sigma_{ik}) = \frac{1}{\sigma_{ik}\sqrt{2\pi}} e^{-\frac{(x-\mu_{ik})^2}{2\sigma_{ik}^2}}$$

**Learning**: estimate the values of the parameters  $\mu_{ik}$ ,  $\sigma_{ik}$  and  $\pi_k = P(Y = y_k)$ .

**Classification** of  $x^{new} = \langle a_1, \ldots a_n \rangle$ 

$$Y^{new} = \arg \max_{y_k} P(Y = y_k) \cdot \prod_i P(X_i = a_i | Y = y_k)$$
  
= arg max<sub>k</sub>  $\pi_k \cdot \prod_i N(a_i | \mu_{ik}, \sigma_{ik})$

#### Maximum Likelihood Estimates

 $\mu_{ik}$  = mean value of  $X_i$  for samples with label  $Y = y_k$ Formally:

$$\mu_{ik} = \frac{\sum_{j} X_{i}^{j} \delta(Y^{j} = y_{k})}{\sum_{j} \delta(Y^{j} = y_{k})}$$

where j ranges over samples in the training set

$$\delta(Y^{j} = y_{k}) = \begin{cases} 1 & \text{se } Y^{j} = y_{k} \\ 0 & \text{altrimenti} \end{cases}$$

 $\sigma_{ik}^2$  = variance of  $X_i$  for samples with label  $Y = y_k$ 

$$\sigma_{ik}^2 = \frac{\sum_j (X_i^j - \mu_{ij})^2 \delta(Y^j = y_k)}{\sum_j \delta(Y^j = y_k)}$$

# Logistic RegressionThe logistic function

イロト 不得 トイラト イラト 一日

Idea:

- Naïve Bayes allows us to compute P(Y|X) after having learned P(Y) and P(X|Y)
- Why not directly learn P(Y|X)?

イロト 不得下 イヨト イヨト 二日

Hypothesis:

- Y boolean random variable
- X<sub>i</sub> continuous random variable
- X<sub>i</sub> independent from each other Y
- $P(X_i|Y = k)$  have Gaussian distributions  $N(\mu_{ik}, \sigma_i)$ (Warning not  $\sigma_{ik}$ !)
- Y has a Bernoulli distribution  $(\pi)$

Then

$$P(Y = 1 | X = \langle x_1 \dots x_n \rangle) = \frac{1}{1 + exp(w_0 + \sum_i w_i x_i)}$$

Proof By hypothesis

$$P(X_i|Y=k) = N(X_i, \mu_{ik}, \sigma_i) = \frac{1}{\sigma_i \sqrt{2\pi}} e^{-\frac{(x-\mu_{ik})^2}{2\sigma_i^2}}$$

Hence:

$$P(Y = 1|X) = \frac{P(Y = 1) \cdot P(X|Y = 1)}{P(Y = 1) \cdot P(X|Y = 1) + P(Y = 0) \cdot P(X|Y = 0)}$$

$$= \frac{1}{1 + \frac{P(Y = 0) \cdot P(X|Y = 0)}{P(Y = 1) \cdot P(X|Y = 1)}}$$

$$= \frac{1}{1 + \exp(ln(\frac{P(Y = 0) \cdot P(X|Y = 0)}{P(Y = 1) \cdot P(X|Y = 1)}))}$$

$$= \frac{1}{1 + \exp(ln\frac{1 - \pi}{\pi} + \sum_{i} ln\frac{P(X_{i}|Y = 0)}{P(X_{i}|Y = 1)})}$$

$$= \frac{1}{1 + \exp(ln\frac{1 - \pi}{\pi} + \sum_{i} (\frac{\mu_{i0} - \mu_{i1}}{\sigma_{i}^{2}}X_{i} + \frac{\mu_{i1}^{2} - \mu_{i0}^{2}}{2\sigma_{i}^{2}})}$$

#### Very useful!

lf

$$P(Y=1|X=\langle x_1\ldots x_n\rangle)=\frac{1}{1+exp(w_0+\sum_i w_i x_i)}$$

then

$$P(Y=0|X=\langle x_1\ldots x_n\rangle)=\frac{exp(w_0+\sum_i w_i x_i)}{1+exp(w_0+\sum_i w_i x_i)}$$

Hence

$$\frac{P(Y=0|X=\langle x_1\ldots x_n\rangle)}{P(Y=1|X=\langle x_1\ldots x_n\rangle)}=exp(w_0+\sum_i w_ix_i)$$

and in particular

$$ln\frac{P(Y=0|X=\langle x_1\ldots x_n\rangle)}{P(Y=1|X=\langle x_1\ldots x_n\rangle)}=w_0+\sum_i w_ix_i$$

To classify  $X = \langle x_1 \dots x_n \rangle$  it suffices to check if  $w_0 + \sum_i w_i x_i > 0$ 

▲□▶ ▲圖▶ ▲臣▶ ▲臣▶ 三臣 - のへ⊙

Logistic regression assumes

$$P(Y=1|X=\langle x_1\ldots x_n\rangle)=\frac{1}{1+exp(-w_0-\sum_i w_i x_i)}$$

and directly tries to estimate the parameters  $w_i$  (the change in sign is ininfluent).

$$\sigma(x) = \frac{1}{1 + e^{-x}}$$

is an important function called logistic function

イロト イポト イヨト イヨト

#### Training for logistic regression (binary case)

We know that

$$P(Y = 1 | x_i w_i) = \sigma(w_0 + \sum_i w_i x_i)$$

Given the (independent) samples  $\langle x_i^\ell, y^\ell \rangle$ , their probability is

$$\prod_{\ell} P(y^{\ell}|x_i^{\ell}w_i) = \prod_{\ell} P(y^{\ell} = 1|x_i^{\ell}w_i)^{y^{\ell}} \cdot P(y^{\ell} = 0|x_i^{\ell}w_i)^{(1-y^{\ell})}$$

We want to find the values for the parameters  $w_i$  that maximize this probability (MLE).

Analogously, we can work on the logarithm and maximize

$$\sum_{\ell} \log P(y^{\ell} | x_i^{\ell} w_i) = \sum_{\ell} (y^{\ell} \cdot \log P(Y = 1 | x_i^{\ell} w_i) + (1 - y^{\ell}) \cdot \log P(Y = 0 | x_i^{\ell} w_i))$$

#### Gradient

Unfortunately, there is no analytic solution for the previous optimization problem.

so, we use iterative optimization methods, like the gradient technique:

$$\nabla_{w}[E] = \begin{bmatrix} \frac{\partial E}{\partial w_{1}}, \dots, \frac{\partial E}{\partial w_{i}} \end{bmatrix}$$
  
training:  $\Delta w_{i} = \mu \cdot \frac{\partial E}{\partial w_{i}}$   
 $w_{i} = w_{i} + \Delta w_{i}$ 

A D N A B N A B N A B N

## The gradient technique

イロト イヨト イヨト イヨト 二日

The objective is to minimize some error function  $\Theta(w)$  on all training examples, suitably adjusting the parameters.

We can reach a minimal configuation for  $\Theta(w)$  by iteratively taking small steps in the direction opposite to the gradient (gradient descent).

This is a general technique.

A D N A B N A B N A B N

Image one "horizontal" axis for each parameter and one "vertical" axis for the error.

For a linear net with a squared error, the surface is a quadratic bowl:

- Vertical cross-sections are parabolas
- Horizontal cross-sections are ellipses

(日)

The error surface for logistic regression is convex too.

For multi-layer, non-linear nets the error surface can be much more complicated (with many local minima).

#### Online vs Batch learning

**Full batch** on all training samples: gradient points to the direction of steepest descent on the error surface (perpendicular to contour lines of the error surface)

**Online** (one sample at a time) gradient zig-zags around the direction of the steepest descent.

(日)

**Mini-batch** (random subset of training samples): a good compromise.

#### Backpropagation can be slow

The gradient does not necessarily points to the direction of the local minimum

・ロト ・ 理 ト ・ ヨ ト ・ ヨ ト ・

#### Gradient for logistic regression

• probability that sample  $\ell$  is in category Y = 1

$$P(Y = 1 | x_i^{\ell} w_i) = \sigma(w_0 + \sum_i w_i x_i^{\ell}) = \alpha^{\ell}$$

Log-likelihood I(w)

$$\sum_{\ell} \log P(Y = y^{\ell} | x_i^{\ell} w_i) = \sum_{\ell} y^{\ell} \log(\alpha^{\ell}) + (1 - y^{\ell}) \log(1 - \alpha^{\ell})$$

gradient (proof on next slide)

$$\frac{\partial I(w)}{\partial w_i} = \sum_{\ell} x_i^{\ell} \cdot (y^{\ell} - \alpha^{\ell})$$

Computing the gradient

$$\alpha^{\ell} = \sigma(z) = \frac{1}{1 + exp(-z)}$$
 where  $z = w_0 + \sum_i w_i x_i^{\ell}$ 

$$\frac{\partial \log(\alpha^{\ell})}{\partial z} = \frac{1}{\alpha^{\ell}} \frac{\partial \alpha^{\ell}}{\partial z} = \frac{\exp(-z)}{1 + \exp(-z)} = 1 - \alpha^{\ell}$$

$$log(1 - \alpha^{\ell}) = log \frac{exp(-z)}{1 + exp(-z)} = -z + log(\alpha^{\ell})$$

$$rac{\partial log(1-lpha^\ell)}{\partial z} = -1 + 1 - lpha^\ell = -lpha^\ell$$

remember that  $\mathit{l}(w) = \sum_{\ell} y^{\ell} \mathit{log}(\alpha^{\ell}) + (1-y^{\ell}) \mathit{log}(1-\alpha^{\ell})$ 

$$\frac{\partial l(w)}{\partial w_i} = \frac{\partial l(w)}{\partial z} \frac{\partial z}{\partial w_i} = (\sum_{\ell} y^{\ell} (1 - \alpha^{\ell}) - (1 - y^{\ell}) \alpha^{\ell}) x_i^{\ell}$$
$$= (\sum_{\ell} (y^{\ell} - \alpha^{\ell})) x_i^{\ell}$$

#### Observation: the derivative of the sigmoid

In the previous slide we proved that

$$rac{\partial \log(lpha^\ell)}{\partial z} = rac{\partial \sigma(z)}{\partial z} = rac{1}{\sigma(z)} rac{\partial \sigma(z)}{\partial z} = 1 - \sigma(z)$$

Hence:

A D N A B N A B N A B N

#### The learning process

Iterate the following update operation until reaching the desired approximation (e.g. until accuracy on testing data is satisfactory, or increment is below a given threshold  $\epsilon$ )

$$w_i \leftarrow w_i + \mu \sum_{\ell} x_i^{\ell} \cdot (y^{\ell} - P(Y = y^{\ell} | x_i w_i))$$

Frequently one add a regularizer (prior):

$$w_i \leftarrow w_i - \frac{\mu \lambda |w_i|}{\mu |w_i|} + \mu \sum_{\ell} x_i^{\ell} \cdot (P(Y = y^{\ell} | x_i w_i) - y^{\ell})$$

helps to keep parameters w<sub>i</sub> close to 0
 tends to reduce overfitting

イロト 不得 トイラト イラト 一日

Let us compare a couple of classification models, according to their predictions:

correct label	1	0	1	0
prediction model 1	.6	.6	.6	.4

## Generative vs discriminative classifiers

(日)

#### Generative vs discriminative methods

Classification: estimate  $f : X \to Y$  or P(Y|X).

#### Generative Classifiers (e.g., Naïve Bayes)

- assume a given distribution for P(X|Y), P(X)
- estimate parameters for P(X|Y), P(X) from training data
- use Bayes' rule to infer P(Y|X)

#### Discriminative Classifiers (e.g., Logistic regression)

- ▶ assume a given distribution for P(Y|X) (or a given shape for the discrimination function)
- estimate the parameters for P(Y|X) (or the discrimination function) from training data

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● のへで

#### Naïve Bayes vs. Logistic regression

**Example:** points with random angle  $0 \le \theta \le \pi$  and random distance .75  $\le r \le 1.25$  from origin.

Input features are the cartesian coordinates of the points (not mutually independent), and we try to discriminate points internal to the unary circle.

#### Naïve Bayes vs.Logistic regression

Same example with 1000 points instead of 100.

logistic regression

gaussian naïve bayes

イロト イボト イヨト イヨ

Similar techniques.

Naïve Bayes is slightly more expressive.

Logistic regression is simpler and makes fewer assumptions on the model.

イロト 不得 トイヨト イヨト 二日
## Cross entropy

## Kullback-Leibler divergence

The Kullback-Leibler divergence DKL(P||Q) between two distributions Q and P, is a measure of the information loss due to approximating P with Q:

$$DKL(P||Q) = \sum_{i} P(i) \log \frac{P(i)}{Q(i)}$$
$$= \sum_{i} P(i) (\log P(i) - \log Q(i))$$
$$= -\underbrace{\mathcal{H}(P)}_{entropy} - \sum_{i} P(i) \log Q(i)$$

We call Cross-Entropy between P and Q the quantity

$$\mathcal{H}(P,Q) = -\sum_{i} P(i) log Q(i) = \mathcal{H}(P) + DKL(P || Q)$$

Let  ${\cal P}$  be the distribution of training data, and  ${\cal Q}$  the distribution induced by the model.

We can take as our learning objective the minimization of the Kullback-Leibler divergence DKL(P||Q).

Since, given the training data, their entropy  $\mathcal{H}(P)$  is constant, minimizing DKL(P||Q) is equivalent to minimizing the cross-entropy  $\mathcal{H}(P, Q)$  between P and Q.

## Cross entropy and log-likelihood

Let us consider the case of a binary classification.

Let  $Q(y = 1|\mathbf{x})$  the probability that  $\mathbf{x}$  is classified 1. Hence,  $Q(y = 0|\mathbf{x}) = 1 - Q(y = 1|\mathbf{x})$ .

The real (observed) classification is  $P(y = 1 | \mathbf{x}) = y$  and similarly  $P(y = 0 | \mathbf{x}) = 1 - y$ .

So we have

$$\begin{aligned} \mathcal{H}(P,Q) &= -\sum_{i} P(i) \log Q(i) \\ &= -y \log (Q(y=1|\mathbf{x})) - (1-y) \log (1-Q(y=1|\mathbf{x})) \end{aligned}$$

...

Classification problems with multiple categories

- means of transport (bus, car, train, bicycle, etc.)
- favourite ice flavor (strawberry, lemon, cream, etc.)
- different characters in writing recognition

Multinomial regression allows us to associate a probability with the different categories, that is particularly useful when combining in cascade different learning techniques.

## Binary case

In the case of binary regression, we assume that the discrimination function between the two cases Y = 0 and Y = 1 is linear:

This is sometimes expressed in terms of the logit function:

Logistic regression is also called binary logit.

#### n-ary case

In the case of multinomial regression with k categories  $\{1, \ldots, k\}$  we have k - 1 equations describing the log-odds of each category with respect to a reference category (e.g. category k):

$$log \frac{P(Y = 1 | \langle x_1 \dots x_n \rangle)}{P(Y = k | \langle x_1 \dots x_n \rangle)} = w_{1,0} + \sum_i w_{1,i} x_i$$
  
...  
$$log \frac{P(Y = k - 1 | \langle x_1 \dots x_n \rangle)}{P(Y = k | \langle x_1 \dots x_n \rangle)} = w_{k-1,0} + \sum_i w_{k-1,i} x_i$$

This model relies on the **Independence of Irrelevant Alternatives** (IIA) assumption:

the odds between two categories A and B are not influenced by a third category C  $\,$ 

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● のへで

## Probability distributions

Let us use a vectorial notation (comprising the constant  $w_0$ )

$$log rac{P(Y=j|\mathbf{x})}{P(Y=k|\mathbf{x})} = \mathbf{w}_j \mathbf{x}$$

Then, for every j

$$P(Y = j | \mathbf{x}) = P(Y = k | \mathbf{x}) \cdot e^{\mathbf{w}_j \mathbf{x}}$$

The sum of probabilities must be 1, that is

$$\sum_{j < k} P(Y = k | \mathbf{x}) \cdot e^{\mathbf{w}_j \mathbf{x}} + P(Y = k | \mathbf{x}) = 1$$

and hence

$$P(Y = k | \mathbf{x}) = \frac{1}{1 + \sum_{j < k} e^{\mathbf{w}_j \mathbf{x}}} \quad \text{and} \quad P(Y = j | \mathbf{x}) = \frac{e^{\mathbf{w}_j \mathbf{x}}}{1 + \sum_{j < k} e^{\mathbf{w}_j \mathbf{x}}}$$

### Comparison with the binary case

Binary case

$$P(Y = 1 | \mathbf{x}) = \frac{1}{1 + e^{\mathsf{wx}}}$$
 and  $P(Y = 0 | \mathbf{x}) = \frac{e^{\mathsf{wx}}}{1 + e^{\mathsf{wx}}}$ 

n-ary case

$$P(Y = k | \mathbf{x}) = \frac{1}{1 + \sum_{j < k} e^{\mathbf{w}_j \mathbf{x}}} \quad \text{and} \quad P(Y = j | \mathbf{x}) = \frac{e^{\mathbf{w}_j \mathbf{x}}}{1 + \sum_{j < k} e^{\mathbf{w}_j \mathbf{x}}}$$

#### There exists a generalization of the logistic function?

### softmax

The function

$$\operatorname{softmax}(j, x_1, \dots, x_k) = \frac{e^{x_j}}{\sum_{j=1}^k e^{x_j}}$$

generalizes the logistic function to the multinomial case. Using softmax, we can express probabilities in the following way

 $P(Y = j | \mathbf{x}) = \operatorname{softmax}(j, \mathbf{w}_1 \mathbf{x}, \dots, \mathbf{w}_{k-1} \mathbf{x}, 0)$ 

It is easy to prove that for any c,

$$\operatorname{softmax}(j, x_1 + c, \dots, x_k + c) = \operatorname{softmax}(j, x_1, \dots, x_k)$$

hence, it is natural to assume that one of the argument (corresponding to the "reference category") is null, taking e.g.  $c = -x_k$ .

The same reasoning shows the irrelevance of the choice of the reference category for computing odds.

## Training

The matrix of parameters  $\mathbf{w}_j$  is computed via maximum likelihood estimation. The probability that a sample  $\langle \mathbf{x}^\ell, y^\ell \rangle$  is correctly classified in the category  $y^\ell$  is

$$P(Y = y^{\ell} | \mathbf{x}) = \prod_{j} P(Y = j | \mathbf{x})^{\delta_{jy^{\ell}}}$$
  
where  $\delta_{ij}$  is the Kronecker  $\delta$ :  $\delta_{ij} := \begin{cases} 1 & \text{if } i = j \\ 0 & \text{if } i \neq j \end{cases}$ 

Supposing that data are independent, their likelihood is the product of individual probabilities. Passing to logarithms:

$$\sum_{l}\sum_{j}\delta_{jy^{\ell}}\cdot \log(P(Y=j|\mathbf{x}))$$

that is usually maximized using a gradient technique.

for sample  $\ell$  you only need to consider the category j corresponding to the true label  $y^{\ell}$ , and the log of the probability  $P(Y = j | \mathbf{x})$  assigned by the model to the sample.

For multinomial regression, the loss function deriving from maximum loglikelihood is the categorical crossentropy between the observed categorical probability  $\delta_{jy^\ell}$  of data (1 for the right category, 0 for others) and that syntesized by the model.

## Gradient for multinomial logistic regression

• probability that sample 
$$\ell$$
 is in category  $Y = j$ 

$$P(Y = j | \mathbf{x}) = \operatorname{softmax}(j, \mathbf{w}_1 \mathbf{x}, \dots, \mathbf{w}_{k-1} \mathbf{x}, 0) = \alpha'_j$$

1

$$\sum_{l}\sum_{j}\delta_{jy^{\ell}}\cdot log(P(Y=j|\mathbf{x}))$$

gradient (feature i and category j)

$$\frac{\partial I(w)}{\partial w_{ij}} = \sum_{\ell} x_i^{\ell} \cdot (y^{\ell} - P(Y = j | \mathbf{x}))$$

# Example: classification of mnist digits with MLR

イロト 不得 トイラト イラト 一日

One may have the erroneous feeling that linear methods are of no real interest, since too weak.

Usually, they becomes interesting when you have a large number of (independent) features at your disposal.

In a high dimensional space training points presumably have a very sparse distribution, hence it may becomes plausible to discriminate classes via hyperplanes.

イロト 不得 トイラト イラト 一日

## Thinking in higher dimensions

The n-ball volume example.

The volume of a d-dimensional sphere of radius r grows as

Kr<sup>d</sup>

for some constant K.

The fraction of the volume of the sphere that lies between radius r = 1 and  $r = 1 - \epsilon$  is

$$\frac{K - K(1 - \epsilon)^d}{K} = 1 - (1 - \epsilon)^d$$

## The volume of a n-ball

The function  $1 - (1 - \epsilon)^d$  for d=1,2,5,20,100

For a really high dimensional sphere, its volume is concentrated in a thin area close to the surface!!

In the case of images, each input digit is a possible feature.

Modified National Institute of Standards and Technology database

- $\blacktriangleright$  grayscale images of handwritten digits, 28  $\times$  28 pixels each
- 60,000 training images and 10,000 testing images

A tiny  $28 \times 28$  image, already has 784 features.

## Weights as images

For each class, the coresponding weights have the same dimensionality of the input image (we have one weight for each feature).

Classification vector for

We can draw them!

<□▶ <□▶ < □▶ < □▶ < □▶ < □ > ○ <

## Linear Regression

## classification predicting a class: Y discrete

## regression predicting a numerical value: Y continuous

**Warning**: the name logistic regression is misleading. Logistic regression is a classification technique.

Learning  $f : X \to Y$  where Y is a real number.

Probabilistic approach:

- choose a distribution P(Y|X), characterized by some parameters  $\theta$
- optimize the parameters θ according to training data (MLE or MAP)

(日)

## Parametric shape of P(Y|X)

Let us assume Y = f(X) up to random, gaussian distributed, noise

 $Y = f(X) + \epsilon$  where  $\epsilon \approx N(0, \sigma)$ 

Hence, Y is a random variable with a distribution

 $p(Y|X) = N(f(X), \sigma)$ 

(日)

with expected value f(x) and standard deviation  $\sigma$ .

## Estimating parameters

$$P(Y|X,W) = N[f(x),\sigma] = \frac{1}{\sigma\sqrt{2\pi}}e^{-\frac{(y-f(x))^2}{2\sigma^2}}$$

Log-likelihood:

$$I(W) = \sum_{\ell} \ln \frac{1}{\sigma\sqrt{2\pi}} - \frac{(y^{\ell} - f(x^{\ell}))^2}{2\sigma^2}$$

Maximizing this quantity is the same as minimizing

$$err(W) = \sum_{\ell} (y^{\ell} - f(x^{\ell}))^2$$

But this is just the sum of squared errors.

## The linear case

If 
$$f(x) = w_0 + w_1(x)$$
, then  

$$err(W) = \sum_{\ell} (y^{\ell} - w_0 - w_1 x^{\ell})^2$$
so  

$$\frac{\partial err(W)}{\partial w_0} = -2 \sum_{\ell} (y^{\ell} - w_0 - w_1(x^{\ell}))$$

$$\frac{\partial err(W)}{\partial w_1} = -2 \sum_{\ell} (y^{\ell} - w_0 - w_1(x^{\ell})) x^{\ell}$$

We can use values for the gradient technique...

or solve the optimization problem analytically.

Equating with 0 the partial derivatives, we get two equations in in two variables:

$$\sum_{\ell} y^{\ell} = \mathsf{N}\mathsf{w}_0 + \mathsf{w}_1 \sum_{\ell} x^{\ell}$$
$$\sum_{\ell} y^{\ell} x^{\ell} = \mathsf{w}_0 \sum_{\ell} x^{\ell} + \mathsf{w}_1 \sum_{\ell} (x^{\ell})^2$$

Let

$$A = \begin{bmatrix} N & \sum_{\ell} x^{\ell} \\ \sum_{\ell} x^{\ell} & \sum_{\ell} (x^{\ell})^{2} \end{bmatrix} \quad W = \begin{bmatrix} w_{0} \\ w_{1} \end{bmatrix} \quad Y = \begin{bmatrix} \sum_{\ell} y^{\ell} \\ \sum_{\ell} y^{\ell} x^{\ell} \end{bmatrix}$$

the previous equations are expressed by the system AW = Y, and hence

 $W = A^{-1}Y$ 

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへで

## Example

Let us look for a linear fitting for the points (1, 2), (2, 3), (6, 4).

$$\sum_{\ell} y^{\ell} = \mathbf{N} \mathbf{w}_0 + \mathbf{w}_1 \sum_{\ell} x^{\ell}$$
$$\sum_{\ell} y^{\ell} x^{\ell} = \mathbf{w}_0 \sum_{\ell} x^{\ell} + \mathbf{w}_1 \sum_{\ell} (x^{\ell})^2$$

In our case,

$$\sum_{\ell} y^{\ell} = 9, N = 3, \sum_{\ell} x^{\ell} = 9$$
$$\sum_{\ell} y^{\ell} x^{\ell} = 32, \sum_{\ell} (x^{\ell})^{2} = 41$$

From which we get the equations

 $9 = 3w_0 + 9w_1$  $32 = 9w_0 + 41w_1$ 

that has solutions  $w_0 = 27/14$  and  $w_1 = 5/14$ 

## Example

Linear fitting for the points (1,2), (2,3), (6,4)

$$y = \frac{27}{14} + \frac{5}{14}x$$

## Instead of minimizing

$$err(W) = \sum_{\ell} (y^{\ell} - f(x^{\ell}))^2$$

### add a regularizer

$$err(W) = \lambda \sum_{i} w_i^2 + \sum_{\ell} (y^{\ell} - f(x^{\ell}))^2$$

(not solvable any longer by analytic means, even in the linear case)

## Network topologies

◆□▶ ◆□▶ ◆目▶ ◆目▶ ▲□ ◆ ��や

If the network is acyclic, it is called a feed-forward network.

If it has cycles it is called recurrent. (no time to talk about them)

●●● Ⅲ → Ⅲ → Ⅲ → Ⅲ → → □ →

In a feed-forward network, neurons are usually organized in layers.

If there is more than one hidden layer the network is deep, otherwise it is called a shallow network.

◆□ ▶ ◆□ ▶ ◆ 臣 ▶ ◆ 臣 ▶ ● 臣 ● のへ⊙

#### Main layers in feed-forward networks: dense layer

**Dense layer**: each neuron at layer k-1 is connected to **each each** neuron at layer k.

A single neuron:

$$I^n \cdot W^n + B^1 = O^1$$

the operation can be vectorized to pruduce *m* outputs in parallel:

$$I^n \cdot W^{n \times m} + B^m = O^m$$

dense layers usually work on flat (unstructured) inputs

the order of elements in input is irrelevant

・ロト・(日下・(日下・(日下・(日下)))

## Main layers in feed-forward networks: convolutional layer

**Convolutional layer**: each neuron at layer k - 1 is connected via a parametric **kernel** to a fixed subset of neurons at layer k. The kernel is convolved over the whole previous layer.

- 1. move the kernel K over a portion M of the input of equal size
- 2. compute the dot product  $M \cdot K$  and possibly add a bias
- 3. shift the kernel and repeat

The dimension of the output only depends from the number of times the kernel is applied.

Input is structured, and the structure is reflected in the output.

## Expressiveness

◆□ ▶ ◆□ ▶ ◆ 臣 ▶ ◆ 臣 ▶ ● 臣 ● のへ⊙

Can we compute any function by means of a Neural Network?

Do we really need **deep** networks?

Can we compute any function with a single neuron?

◆□ ▶ ◆□ ▶ ◆三 ▶ ◆三 ▶ ○ ● ● ● ●

## Single layer case: the perceptron

Binary threshold:

Remark: the bias set the position of threshold.

▲□▶ ▲圖▶ ▲≣▶ ▲≣▶ = 三 のへの

The set of points

$$\sum_i w_i x_i + b = 0$$

defines a hyperplane in the space of the variables  $x_i$ 

The hyperplane

$$\sum_i w_i x_i + b = 0$$

divides the space in two parts: to one of them (above the line) the perceptron gives value 1, to the other (below the line) value 0.

"above" and "below" can be inverted by just inverting parameters:

$$\sum_{i} w_{i} x_{i} + b \leq 0 \iff \sum_{i} -w_{i} x_{i} - b \geq 0$$

◆□▶ ◆□▶ ◆目▶ ◆目▶ ◆□▶

#### Computing logical connectives: NAND

Can we implement this function (NAND) with a perceptron?

<i>x</i> <sub>1</sub>	<i>x</i> <sub>2</sub>	output

### Training

◆□ ▶ ◆□ ▶ ◆臣 ▶ ◆臣 ▶ ○臣 ○ のへ⊙

#### Current loss

Suppose to have a neural network with some configurations of the parameters  $\theta$ .

We can take a **batch** of data, pass them (in parallel) through the network, compute the output, and evaluate the current loss relative to  $\theta$ .

This is a **forward pass** through the network.

◆□▶ ◆□▶ ◆三▶ ◆三▶ ○○ ○○

#### Parameter updating

Next, we would like to adjust the parameters in such a way to decrease the current loss.

Each parameter should deserve a different adjustment, some of them positive, other negative.

The mathematical tool that allows us to establish in which way parameters should be updated is the **gradient**: a vector of **partial derivatives**.

・ロ・・日・・日・・日・・日・

#### Backpropagation

The gradient is computed **backward**, **backpropagating** the loss to all neurons inside a networks, and their connections.

This is a **backward pass** through the network.

The algorithm for computing parameters updates is known as **backpropagation algorithm**.

◆□▶ ◆□▶ ◆三▶ ◆三▶ ● 三 ● 今へ⊙

The backpropagation algorithms only gives a **direction** in which gradients should be updated.

The actual amount of the update is obtained by multiplication with a scalar hyperparameter (fixed externally, not learned) called **learning rate**.

Increasing the learning rate can make training faster, but it reduces the accuracy of the result.

If we make large steps nearby the optimum, we can miss it.

▲□▶▲□▶▲目▶▲目▶ 目 のへの

#### Optimizer

Many techniques can be used to **tune** the learning rate during training.

The tool in charge of governing the gradient descent technique - possibly dynamically adapting the learning rate - is the so called **optimizer** (e.g. Adam, in our example).

Many possibilites:

- Use a fixed learning rate
- adapt the global learning rate during time
- adapt the learning rate on each connection separately
- use the so called momentum

- . . .

suggested lecture: Geoffrey Hinton's lecture

◆□ > ◆□ > ◆三 > ◆三 > ◆□ > ◆○ >

Parameters are updated every time a batch is processed.

During an epoch, we make a total number of updates equal to the size of the training set divided by the batchsize.

If we decrease the batchsize we update more frequently (that is good), but updates are less accurate, since we are backpropagating form a loss relative to very specific data.

Conversely, if we increase the batchsize, updates grow in accuracy (the ideal would be to compute them on the whole training set - **fullbatch**) but training can be slow, since parameters are too rarely updated.

#### Fullbatch, Online and MiniBatch

**Fullbatch** (all training samples): the gradient points to the direction of steepest descent on the error surface (perpendicular to contour lines of the error surface)

**Online** (one sample at a time) gradient zig-zags around the direction of the steepest descent.

**Minibatch** (random subset of training samples): a good compromise.

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ▶ ◆ □ ▶

# The Backpropagation algorithm (and its problems)

A neural network computes a complex function resulting from the composition of many neural layers. How can we compute the gradient w.r.t. a specific parameter (weight) of the net?

We need a mathematical rule know as the chain rule (for derivatives).

●●● Ⅲ ▲田▼ ▲田▼ ▲国▼ ▲日▼

#### The chain rule

Given two derivable functions f, g with derivatives f' and g', the derivative of the composite function h(x) = f(g(x)) is

h'(x) = f'(g(x)) \* g'(x))

Equivalently, letting y = g(x),

h'(x) = f'(g(x)) \* g'(x)) = f'(y) \* g'(x)

The derivative of a **composition** of a sequence of functions is the **product** of the derivatives of the individual functions.

**QUESTION**: why binary thresholding is not a good activation function for backpropagation?

・ロト・日本・モート ヨー うへの

#### Backpropagation rules in vectorial notation

Given some error function E (e.g. euclidean distance) let us define the error derivative at l as the following vector of partial derivatives:

$$\delta' = \frac{\partial E}{\partial z'}$$

We have the following equations

where  $\odot$  is the Hadamard product (component-wise)

$$(BP2) \quad \delta' = (w'^{+1})^T \delta'^{+1} \odot \sigma'(z')$$

By the chain rule, the derivative is a long sequence of factors, where these factors are, alternately

- derivatives of activation functions
- derivative of linear functions, that are constants (in fact, the transposed matrix of the linear coefficients)

Let's have a look at the derivatives of a couple of activation functions.

#### Derivatives of common activation functions

Observe the flat shape of  $\sigma'(x)$ , always below 0.25

Relu

If you systematically use the sigmoid as activation function in all layers of a deep network, the gradient will contain a lot of factors below 0.25, resulting in a very small value.

If the gradient is close to zero, learning is impossible.

This is known as the vanishing gradient problem.

●●● Ⅲ ▲田▼ ▲田▼ ▲国▼ ▲日▼

The vanishing gradient problem blocked the progress on neural netwoks for almost 15 years (1990-2005).

It was first bypassed by network pre-training (e.g. with Boltzmann Machines), and later by the introduction on new activation functions, such as Rectified Linear Units (RELU), making pre-training obsolete.

Still, fine-tuning starting from good network weights (e.g. VGG) is a viable approach for many problems (transfer learning).

Loose connectivity and shared weights

- the activation of a neuron is not influenced from all neurons of the previous layer, but only from a small subset of adjacent neurons: his receptive field
- every neuron works as a convolutional filter. Weights are shared: every neuron perform the same trasformation on different areas of its input
- with a cascade of convolutional filters intermixed with activation functions we get complex non-linear filters assembing local features of the image into a global structure.

#### Images as surfaces

イロト イヨト イヨト イヨト

Edges, angles, ...: points where there is a discontinuity, i.e. a fast variation of the intensity

More generally, are interested to identify patterns inside the image. The key idea is that the kernel of the convolution expresses the pattern we are looking for.

A D N A B N A B N A B N

Suppose we want to find the positions inside the image where there is a sudden horizontal passage from a dark region to a bright one. The pattern we are looking for is

 $\left[\begin{array}{cc} -1 & 1 \end{array}\right]$ 

or, varying the distance between pixels:

 $\left[\begin{array}{rrr} -1 & 0 & 1 \end{array}\right]$ 

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● のへで

#### The finite derivative at work

Each neuron in a convolutional layer gets activated by specific patterns in the input image.

◆□▶ ◆圖▶ ◆臣▶ ◆臣▶ ○臣

## Another example: the finite laplacian

イロト イヨト イヨト イヨト

But how to find good patterns?

Usual idea:

instead of using human designed pre-defined patterns, let the net learn them.

Particularly important in deep architectures, because:

- stacking kernels we enlarge their receptive fields (see next slide)
- adding non-linear activations we synthesize complex, non-linear kernels

The receptive field of a (deep, hidden) neuron is the dimension of the input region influencing it.

It is equal to the dimension of an input image producing (without padding) an output with dimension 1.

イロト イポト イヨト イヨト

#### A neuron cannot see anything outside its receptive field!

We may also rapidly enlarge the receptive fields by means of **downsampling** layers, e.g. pooling layers or convolutional layers with non-unitarian stride

The intuition is that neurons at higher layers should recognize increasingly complex patterns, obtained as a combination of previous patterns, over a larger receptive field.

In the highest layers, neurons may start recognizing patterns similar to features of objects in the dataset, such as feathers, eyes, etc.

In the final layers, neurons gets activated by "patterns" identifying objects in the category.

#### can we confirm such a claim?

(日)

## How CNNs see the world

(日)

Goal: find a way to visualize the kind of patterns a specific neuron gets activated by.

The loss function  $\mathcal{L}(\theta, x)$  of a NN depends on the parameters  $\theta$  and the input x.

During training, we fix x and compute the partial derivative of  $\mathcal{L}(\theta, x)$  w.r.t the parameters  $\theta$  to adjust them in order to decrease the loss.

In the same way, we can fix  $\theta$  and use partial derivatives w.r.t. input pixels in order to syntehsize images minimizing the loss.

#### Andrea Asperti Università di Bologna - DISI: Dipartimento di Informatica: Scienza e Ingegneria 22

Goal: find a way to visualize the kind of patterns a specific neuron gets activated by.

イロト 不得 トイヨト イヨト

The loss function  $\mathcal{L}(\theta, x)$  of a NN depends on the parameters  $\theta$  and the input x.

During training, we fix x and compute the partial derivative of  $\mathcal{L}(\theta, x)$  w.r.t the parameters  $\theta$  to adjust them in order to decrease the loss.

In the same way, we can fix  $\theta$  and use partial derivatives w.r.t. input pixels in order to syntehsize images minimizing the loss.

Start with a random image, e.g.

イロト イヨト イヨト イヨト 二日

- do a forward pass using this image x as input to the network to compute the activation a<sub>i</sub>(x) caused by x at some neuron (or at a whole layer)
- ▶ do a backward pass to compute the gradient of ∂a<sub>i</sub>(x)/∂x of a<sub>i</sub>(x) with respect to each pixel of the input image
- ► modify the image adding a small percentage of the gradient ∂a<sub>i</sub>(x)/∂x and repeat the process until we get a sufficiently high activation of the neuron

## First layers

Some neurons from the first two layers of AlexNet (Understanding Neural Networks Through Deep Visualization by A.Nguyen et al., 2015)

First features (lower picture) are very simple, and get via via more complex at higher levels, as their receptive field get larger due to nested convolutions.

イロト イポト イヨト イヨト

## First layers

For a visualization of the first layers of VGG see:

An exploration of convnet filter with keras

## What caused the activation of this neuron in this image?

Instead of trying to syntesize the pattern recognized by a given neuron, we can use the gradient ascent technique to emphasize in real images what is causing its activation.

Visualizing and Understanding Convolutional Networks Matthew D Zeiler, Rob Fergus (2013)

## Tensors for 2D processing

イロト イヨト イヨト イヨト 三日

Convolutional Networks process Tensors. A Tensor is just an multidimensional array of floating numbers.

The typical tensor for 2D images has **four** dimensions:

 $\textit{batchsize} \times \textit{width} \times \textit{height} \times \textit{channels}$ 

Features maps are **stacked** along the channel dimension. At start, for a color image, we just have 3 channels: r,g,b.

How do kernel operate along the channel dimension?

イロト イヨト イヨト イヨト 三日

Convolutional Networks process Tensors. A Tensor is just an multidimensional array of floating numbers.

The typical tensor for 2D images has **four** dimensions:

 $\textit{batchsize} \times \textit{width} \times \textit{height} \times \textit{channels}$ 

Features maps are **stacked** along the channel dimension. At start, for a color image, we just have 3 channels: r,g,b.

How do kernel operate along the channel dimension?

#### Dense processing along channel axis

Unless stated differently (e.g. in separable convolutions), a filter operates on all input channels in parallel.

So, if the input layer has depth D, and the kernel spatial size is NxM, the actual dimension of the kernel will be

**N**xMxD

(日)

# The convolution kernel is tasked with simultaneously mapping cross-channel correlations and spatial correlations

Each kernel produces a single feature map.

Feature maps produced by different kernels are stacked along the channel dimension: the number of kernels is equal to the channel-**depth** of the next layer.

The **spatial** dimension of the feature map depends from two configurable factors:

- paddding: extra space added around the input
- **stride**: kernel deplacement over the input during convolution

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● のへで

#### Relevant parameters for convolutional layers

- **kernel size**: the dimension of the linear filter.
- stride: movement of the linear filter. With a low stride (e.g. unitary) receptive fields largely overlap. With a higher stride, we have less overlap and the dimension of the output get smaller (lower sampling rate).
- padding Artificial enlargement of the input to allow the application of filters on borders.

 depth: number of features maps (stacked along the so called channel axis) that are processed in parallel. The depth of the output layer depends from the number of different kernels that we want to synthesize (each producing a different feature map).

Along each axes the dimension of the output is given by the following formula

$$\frac{W+P-K}{S}+1$$

where:

- W = dimension of the input
- $\mathsf{P} = \mathsf{padding}$
- K = Kernel size
- $\mathsf{S}=\mathsf{Stride}$

In deep convolutional networks, it is common practice to alternate convolutional layers with pooling layers, where each neuron simply takes the mean or maximal value in its receptive field.

This has a double advantage:

- it reduces the dimension of the output
- it gives some tolerance to translations

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

Not well understood yet.

The usual explanation is that during back propagation, **the gradient at higher layers can easily pass to lower layers**, withouth being mediated by the weight layers, which may cause vanishing gradient or exploding gradient problem.

イロト イヨト イヨト イヨト 三日

The "sum" operation can be interpreted in a liberal way. A common variant consists in concatenating instead of adding (usually along the channel axis):

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

# Transfer Learning

イロト イヨト イヨト イヨト

We learned that the first layers of convolutional networks for computer vision compute feature maps of the original image of growing complexity.

The filters that have been learned (in particular, the most primitive ones) are likely to be independent from the particular kind of images they have been trained on.

They have been trained on a huge amount of data and are probably very good.

It is a good idea to try to *reuse them* for other classification tasks.

# How to fool a Neural Networks

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● のへで

In an image classification framework, we can use the **gradient ascent technique** to increase, starting from noise or any given picture, the score of whatever class we want.

#### Demo!

We shall try to transform an elephant into a tigershark.

3

# Fooling Neural Networks

Since we have many pixels, a tiny (imperceptible to humans!), consistent perturbation of all of them is able to fool the classifier.

#### Intriguing Properties of Neural Networks, C. Szegedy et al., 2013

(日)

## A different technique

The previous technique, being based on gradient ascent, requires the knowledge of the neural net in order to fool it.

We can do something similar using the network as a **black box**, for instance by means of evolutionary techniques

- Nguyen A, Yosinski J, Clune J. Deep Neural Networks are Easily Fooled. In Computer Vision and Pattern Recognition (CVPR '15), IEEE, 2015.

They were able to produce not only "noisy" adversarial images, but also geometrical examples with high regularities (meaningful for humans).

# Evolutionary approach

Figure 2. Although state-of-the-art deep neural networks can increasingly recognize natural images (*left panel*), they also are easily fooled into declaring with near-certainty that unrecognizable images are familiar objects (*center*). Images that fool DNNs are produced by evolutionary algorithms (*right panel*) that optimize images to generate high-confidence DNN predictions for each class in the dataset the DNN is trained on (here, ImageNet).

- start with a random population of images
- alternately apply selection (keep best) and mutation (random perturbation/crossover)

イロト 不得 トイヨト イヨト 二日

# Why classification techniques are vulnerable

7

A D N A B N A B N A B N

# Why classification techniques are vulnerable

• **discriminating** between domains does not give us much knowledge about those domains.

Difference between **generative** and **discriminative** approaches in machine learning.

• if data occupy a **low-dimensional** portion in the feature space, it is easy to modify features, to pass the borders of our discrimination boundaries.

In the next slides we try to better understand these concepts.

(日)

# NN for image processing

A Neural Network for image processing has a structure of the following kind (this is Inception V3):

- a long sequence of convolutional layers, possibly organized in suitable modules (e.g. inception modules)
- ► a **short** (2 or 3) final sequence of dense layers

< □ > < □ > < □ > < □ > < □ > < □ >

- with convolutional layers we extract interesting features from the input image, generating a different internal representation of data in terms of these features
- with the dense layers, we exploit these features in view of the particular problem we are aiming to solve (e.g. classification).

< □ > < □ > < □ > < □ > < □ > < □ >

Reversing the representation of data makes sense as far as we are in extraction phase

- we can syntesize interesting patterns recognized by neurons of convolutional layers

We cannot expect to derive interesting information about categories from the information that the network uses to discriminate among them.

 we cannot automatically synthesize a "cat" (starting from a classifier; we shall see specific generative techniques in the next lesson)

The previous point explains why we should not expect to be able to syntesize images of high level categories starting from a classifier.

But it does not explain why an almost imperceptible modification of an image is enough to fool the classifier.

To answer to this question we must discuss the dimensionality of the data manifold.

If we generate an image at random, it looks like noise.

The probability of randomly generating an image having some sense for us **is null**.

イロト イポト イヨト イヨト 二日

This means that "natural images" occupy a portion of the features space of almost **no dimension**.

Moreover, due their regularities, we expect them to be organized along some **disciplined**, **smooth-runnning** surfaces.

This is the so called **manifold** of data (in the features space).

Suppose we have a space with two features, and our data occupy the manyfold of dimension 1, along the dotted line described in the following picture.

Suppose moreover that our data are splitted in two categories (yellow and blue) and we want to perform their classification

A D N A B N A B N A B N

### The Manifold issue

We have little knowledge of where the classifier will draw the boundary.

A tiny change in the data features may easily result in a missclassification.

A D N A B N A B N A B N

Now imagine the possibilities in a space with hundreads or thousands of dimensions.

Observe that we are escaping from the actual data manifold.

The complexity of inceptionims consists in modifying an image remaining inside the expected data manifold.

This is difficult, since we have little knowldge about the actual data distribution in the feature space.

To this aim, deepdream generator exploits **regularization** techniques (smoothing, texture similarities, etc.) trying to obtain images similar (in statistical terms) to those in the training set.

イロト 不得 トイヨト イヨト

# Autoencoders

イロト イヨト イヨト イヨト 三日

Two natural questions about the data manifold:

- We said that (in frequent cases) the actual dimensionality of the data manifold is low in comparison with the latent space. Can we experimentally confirm this claim? Can we compress data?
- For fooling networks, we synthesized new samples **outside** the actual data manifold.
   Is it possible to **automatically detect** this kind of **anomalies**?

To answer to these kind of questions it is worth to have a look at particular neural network models called **autoencoders**.

An autoencoder is a net trained to reconstruct input data out of a learned internal representation

Usually, the internal representation has lower dimensionallity w.r.t. the input

イロト イポト イヨト イヨト

#### Why is data compression possible, in general?

Because we exploit **regularities** (correlations) in the features describing input data.

If the input has a random structure (high **entropy**) no compression is possible

- random, lawless, uncompressible, high entropy
- ordered, lawfull, compressible, low entropy

#### <ロト < 回 ト < 臣 ト < 臣 ト 三 の < C</p>
Why is data compression possible, in general?

Because we exploit  $\ensuremath{\textit{regularities}}$  (correlations) in the features describing input data.

If the input has a random structure (high **entropy**) no compression is possible

- random, lawless, uncompressible, high entropy
- ordered, lawfull, compressible, low entropy

If (as usual) the internal layer has fewer units of the input, autoencoders can be seen as a form data compression. The compression is

- data-specific: it only works well on data with strong correlations (e.g. digits, faces, etc.) This is different from traditional data compression algorithms
- lossy: the output is degraded with respect to the input. This is different from textual compression algorithms, such as gzip
- directly trained on unlabeled data samples. We usually talk of self-supervised training

Non so good for data compression, due to the lossy nature.

Applications to

- data denoising
- anomaly detection
- feature extraction (generalization of PCA)
- generative models (VAE)

Especially, an amusing and simple to understand topic.

Denoising autoencoders inspired dropout

イロト 不得 トイラト イラト 一日

## Anomaly detection

A D N A B N A B N A B N

The latent encoding of data is meant to capture the **main components** of the data features.

We can hence expect to **easily detect anomalies** by looking at points with **abnormal latent values**.

Equivalently, we may look at points with a **reconstruction below the expected quality**.

・ロト ・聞 ト ・ ヨト ・ ヨト … ヨ

Autoencoding is **data specific**: the autoencoder works well on data similar to those it was trained on.

If applied on different data (anomaly), it will perform poorly.

Example on mnist data with the autoencoder of the previous demo. mean loss = 0.105, std: 0.036

イロト 不得 トイラト イラト 一日

## Generative Models

◆□ ▶ ◆□ ▶ ◆ 臣 ▶ ◆ 臣 ▶ ● 臣 ● のへ⊙

**Generative Model**: a model that tries to learn the actual distribution  $p_{data}$  of real data from available samples (training set).

**Goal**: build probability distribution  $p_{model}$  close to  $p_{data}$ .

We can either try to

- explicitly estimate the distribution
- build a generator able to sample according to p<sub>model</sub>, possibly providing estimations of the likelihood

#### Why studying Generative Models?

- improve our knowledge on data and their distribution in the visible feature space
- improve our knowledge on the latent representation of data and the encoding of complex high-dimensional distributions
- tipical approach in many problems involving multi-modal outputs
- find a way to produce realistic samples from a given probability distribution
- generative models can be incorporated into reinforcement learning, e.g. to predict possible futures

In many interesting cases there is **no unique intended solution** to a given problem:

- add colors to a gray-scale image
- guess the next word in a sentence
- fill a missing information
- predict the next state/position in a game

- ...

When the output is intrinsically multi-modal (and we do not want to give up to the possibility to produce multiple outputs) we need to rely on generative modeling.

・ロ・・日・・日・・日・ シック・

In latent variable models we express the probability of a data point X through marginalization over a vector of latent variables:

$$P(X) = \int P(X|z)P(z)dz \approx \mathop{\mathbb{E}}_{z \sim P(z)} P(X|z)$$
(1)

This simply means that we try to learn a way to sample X starting from a vector of values z (this is P(X|z)), where z is distributed with a **know prior** distribution P(z). z is the **latent encoding** of X.

▲□▶▲□▶▲≣▶▲≣▶ ■ のへの

#### Generative models

There are four main classes of generative models:

- compressive models
  - Variational Autoencoders (VAEs)
  - Generative Adversarial Networks (GANs)
- dimension preserving models
  - Normalizing Flows
  - Denoising Diffusion Models

The models differ in the way the generator is trained

$$\begin{array}{c} \hline z \sim P(z) \longrightarrow \end{array} \begin{array}{c} \text{Generator} \\ P(X \mid z) \longrightarrow \\ \hline X \end{array}$$

・ロ・・日・・日・・日・ シック・

In a Variational Autoencoder the generator is coupled with an **encoder** producing a latent encoding z given X. This will be distributed according to an inference distribution Q(z|X).

$$X \longrightarrow \begin{bmatrix} \text{Encoder} \\ Q(z \mid X) \end{bmatrix} \xrightarrow{} z \sim P(z) \longrightarrow \begin{bmatrix} \text{Generator} \\ P(X \mid z) \end{bmatrix} \xrightarrow{} \widehat{X}$$

The loss function aims to:

- minimize the reconstruction error between X and  $\widehat{X}$
- bring the marginal inference distribution Q(z) close to the prior P(z)

In a Generative Adversarial Network, the generator is coupled with a **discriminator** trying to tell apart **real** data from **fake** data produced by the generator.

Detector and Generator are trained together.

The loss function aims to:

- instruct the detector to spot the generator
- instruct the generator to fool the detector

### Normalizing Flows

In Normalizing Flows the generator is split into a long chain of *invertible* transformations.

The network is trained by maximizing loglikelihood.

- Pros: it allows a precise computation of the resulting loglikelihood
- Cons: the fact of restricting to invertible transformation limit the expressiveness of the model

#### Diffusion Models

In Diffusion Models the latent space is understood as a strongly noised version of the image to be generated.

The generator is split into a long chain of *denoising steps*, where each step t attempts to remove gaussian noise with a given variance  $\sigma_t$ .

We train a single network implementing the denoising operation, parametric in  $\sigma_t.$

#### Variational autoencoder

In a Variational Autoencoder (VAE) we try **to force** latent variables to have a known prior distribution P(z) (e.g. a Normal distribution)

If the distribution computed by the generator is Q(z|X) we try to force the marginal distribution  $Q(z) = \mathbb{E}_{X \sim P_{data}} Q(z|X)$  to look like a normal distribution.

◆□ ▶ ◆□ ▶ ◆ 臣 ▶ ◆ 臣 ▶ ● 臣 ● のへ⊙

#### Different moments for each point

We assume Q(z|X) has a Gaussian distribution  $G(\mu(X), \sigma(X))$  with different moments for each different input X.

The values  $\mu(X)$ ,  $\sigma(X)$  are both computed by the generator, that is hence returning an **encoding**  $z = \mu(X)$  and a variance  $\sigma(X)$ around it, expressing the portion of the latent space essentially encoding an information similar to X.

#### Sampling in the latent space

During training, we sample around  $\mu(X)$  with the computed  $\sigma(X)$  before passing the value to the decoder

Among other things, sampling add noise to the encoding, improving its robustness.

#### The full picture

 $\mu(X)$  and  $\Sigma(X)$  are not used to generate new samples from the input domain (we have no X)

◆□▶ ◆□▶ ◆目▶ ◆目▶ ▲□ ◆ ��や

#### The effect of KL-divergence

The effect of the KL-divergence on latent variables consist in

- pushing µ<sub>z</sub>(X) towards 0, so as to center the latent space around the origin
- push σ<sub>z</sub>(X) towards 1, augmenting the "coverage" of the latent space, essential for generative purposes.

## Generative Adversarial Networks

Suggested reading: NIPS 2016 Tutorial: Generative Adversarial Networks

◆□ > ◆□ > ◆三 > ◆三 > ◆□ > ◆○ >

#### The GAN approach: a two player game

A game between the generator and the discriminator

Generative Adversarial Networks I.J.Goodfellow et al., 2014

▲□▶ ▲圖▶ ▲≣▶ ▲≣▶ = 三 - のへの

#### $Min_G Max_D V(D, G)$

 $V(D,G) = \mathbb{E}_{x \sim p_{data}(x)}[\log D(x)] + \mathbb{E}_{z \sim p_z(z)}[\log (1 - D(G(z)))]$ 

- ► E<sub>x∼Pdata</sub>(x)[log D(x)] = negative cross entropy of the discriminator w.r.t the true data distribution
- $\mathbb{E}_{z \sim p_z(z)}[log(1 D(G(z)))] =$  negative cross entropy of the "false" discriminator w.r.t the fake generator

#### Training

Alternately train the discriminator, freezing the generator, and the generator freezing the discriminator:

for number of training iterations do

for k steps do

- Sample minibatch of m noise samples  $\{z^{(1)}, \ldots, z^{(m)}\}$  from noise prior  $p_q(z)$ .
- Sample minibatch of m examples  $\{x^{(1)}, \ldots, x^{(m)}\}$  from data generating distribution  $p_{data}(\boldsymbol{x})$ .
- Update the discriminator by ascending its stochastic gradient;

$$\nabla_{\theta_d} \frac{1}{m} \sum_{i=1}^m \left[ \log D\left( \boldsymbol{x}^{(i)} \right) + \log \left( 1 - D\left( G\left( \boldsymbol{z}^{(i)} \right) \right) \right) \right].$$

end for

- Sample minibatch of m noise samples  $\{z^{(1)}, \ldots, z^{(m)}\}$  from noise prior  $p_q(z)$ .
- · Update the generator by descending its stochastic gradient:

$$\nabla_{\theta_g} \frac{1}{m} \sum_{i=1}^{m} \log \left(1 - D\left(G\left(\boldsymbol{z}^{(i)}\right)\right)\right).$$

#### end for

The gradient-based updates can use any standard gradient-based learning rule. We used momentum in our experiments.

#### An example

Figure 1: Generative adversarial nets are trained by simultaneously updating the discriminative distribution (D, blue, dashed line) so that it discriminates between samples from the data generating distribution (D, blue, dashed line) so that it discriminates between samples from the data generating distribution (black, dotted line)  $p_x$  from those of the generative distribution  $p_g$  (G) (green, solid line). The lower horizontal line is the domain from which z is sampled, in this case uniformly. The horizontal line above is part of the domain of x. The upward arrows show how the mapping x = G(z) imposes the non-uniform distribution  $p_g$  on transformed samples. G contracts in regions of high density and expands in regions of low density of  $p_g$ . (a) Consider an adversarial pair near convergence:  $p_g$  is similar to  $p_{data}$  and D is a partially accurate classifier. (b) In the inner loop of the algorithm D is trained to discriminate samples from data, converging to  $D^*(x) = \frac{p_{lam}(x)}{p_{lam}(x) + p_{lam}(x)}$ . (c) After an update to G, gradient of D has guided G(z) to flow to regions that are more likely to be classified as data. (d) After several steps of training, if G and D have enough capacity, they will reach a point at which both cannot improve because  $p_g = p_{data}$ . The discriminator is unable to differentiate between the two distributions, i.e.  $D(x) = \frac{1}{2}$ .

## An application: face generation

**Goal**: Generation of plausible realistic photographs of human faces.

## Face generation video by Nvidia

- the fact that the discriminator get fooled does not mean the fake is good (neural networks are easily fooled)
- problems with counting, perspective, global structure, ...
- mode collapse: generative specialization on a good, fixed sample

See Ian Goodfellows' slides

## Latent space exploration

#### Interpreting the Latent Space of GANs for Semantic Face Editing

## Attribute editing

The generative process is **continuous**: a small deplacement in the latent space produces a small modification in the visible space.

Real-world data depends on a relatively **small number of explanatory factors of variation** (latent features) providing compressed internal representations.

Understanding these features we may define **trajectories** producing desired alterations of data in the visible space.

●●● Ⅲ ▲田▼ ▲田▼ ▲国▼ ▲日▼

## Entanglement and disentanglement

When there is more than one attribute, editing one may affect another since some semantics can be coupled with each other (entanglement).

To achieve more precise control (disentanglement), we can use projections to force the different directions of variation to be orthogonal to each other.

▲□▶▲圖▶▲≣▶▲≣▶ ≣ のQ@

## Comparing spaces

▲□▶ ▲□▶ ▲目▶ ▲目▶ 目 のへで

We can pass from a latent space to another by means of a simple **linear map** preserving most of the content.

The organization of the latent space seems to be independent from

- the training process
- the network architecture
- ▶ the learning objective: GAN and VAE share the same space!

The map can be defined by a small set of points common to the two spaces: the **support set**. Locating these points in the two spaces is enough to define the map.

See also my blog for a discussion.

# Diffusion models

Generative Reverse Denoising Process

#### Suggested reading: What are diffusion models

◆□ > ◆□ > ◆三 > ◆三 > ◆□ > ◆○ >

## The denoising network

The denoising network implements the inverse of the operation of adding a given amount of noise to an image (direct diffusion).

The denoising network takes in input:

- 1. a noisy image  $x_t$
- 2. a signal rate  $\alpha_t$  expressing the amount of the original signal remaining in the noisy image

and try to predict the noise in it:

 $\epsilon_{\theta}(\mathbf{x}_t, \alpha_t)$ 

The predicted image would be:

$$\hat{x_0} = (x_t - \sqrt{1 - \alpha_t} \cdot \epsilon_{\theta}(x_t, \alpha_t)) / \sqrt{\alpha_t}$$

## Training step

- take an input image  $x_0$  in the training set and normalize it
- consider a signal ratio  $lpha_t$
- generate a random noise  $\epsilon \sim \textit{N}(0,1)$
- generate a noisy version  $x_t$  of  $x_0$  defined as

$$x_t = \sqrt{\alpha_t} \cdot x_0 + \sqrt{1 - \alpha_t} \cdot \epsilon$$

- let the network predict the noise  $\epsilon_{\theta}(x_t, \alpha_t)$  from the noisy image  $x_t$  and the signal ratio  $\alpha_t$
- train the network to minimize the prediction error, namely

$$\|\epsilon - \epsilon_{\theta}(\mathbf{x}_t, \alpha_t)\|$$

- fix a sheduling  $\alpha_T > \alpha_{T-1} > \ldots > \alpha_1$
- start with a random noisy image  $x_{\mathcal{T}} \sim \mathcal{N}(0,1)$
- for t in T...1 do:
- compute the predicted error  $\epsilon_{\theta}(x_t, \alpha_t)$
- compute  $\hat{x_0} = (x_t \sqrt{1 \alpha_t} \cdot \epsilon_{\theta}(x_t, \alpha_t)) / \sqrt{\alpha_t}$
- if  $t \neq 0$ , obtain  $x_{t-1}$  reinjecting noise at rate  $\alpha_{t-1}$ , namely

$$x_{t-1} = \sqrt{\alpha_{t-1}} \cdot \hat{x_0} + \sqrt{1 - \alpha_{t-1}} \cdot \epsilon$$

# YOLO's architecture

Suggested reading: Yolo-tutorial in pytorch

●●● Ⅲ → Ⅲ → Ⅲ → Ⅲ → → □ →

Yolo is a Fully Convolutional Networks. The input is progressively downsampled by a factor  $2^5 = 32$ .

For instance, an input image of dimension 416x416 would be reduced to a grid of neurons of dimension 13x13: the **feature map** 

◆□ > ◆□ > ◆三 > ◆三 > ◆□ > ◆○ >

### Which neuron is in charge of detection?

Detection of an object may concern all neurons inside the bounding box.

#### So, who's in charge for detection?

The answer crucially influences the way the network should be trained.

In YOLO, a single neuron is responsible for detection: the one whose grid-cell contains the center of the bounding box.

This neuron makes a finite number of **predictions** (e.g. 3).

▲□▶ ▲□▶ ▲目▶ ▲目▶ 目 のへぐ

#### Predictions

Image Grid. The Red Grid is responsible for detecting the dog

We have  $13 \times 13$  neurons in the feature map.

Depth-wise, we have  $(B \times (5 + C))$ entries, where B represents the number of bounding boxes each cell can predict (say, 3), and C is the number of different object categories.

Each bounding box has 5 + C attributes, which describe the center coordinates (2), the dimensions (2), the objectness score (1) and C class confidences.

Trying to directly predict width and the height of the bounding box leads to **unstable gradients** during training.

Most of the modern object detectors predict log-space affine transforms for **pre-defined** default bounding boxes called **anchors**.

Then, these transforms are applied to the anchor boxes to obtain the prediction. YOLO v3 has three anchors, which result in prediction of three bounding boxes per cell.

The bounding box responsible for detecting the object is one whose anchor has the highest IoU with the ground truth box.

Objectness score represents the probability that an object is contained inside a bounding box.

The objectness score is also passed through a sigmoid, as it is to be interpreted as a probability.

●●● Ⅲ → Ⅲ → Ⅲ → Ⅲ → → □ →

Class confidences represent the probabilities of the detected object belonging to a particular class. Before v3, YOLO class scores were computed via a softmax.

Since YOLOv3, multiple sigmoid functions are used instead, considering that objects may belong to multiple (hierachical) categories, and hence labels are not guaranteed to be mutually exclusive.

●●● Ⅲ → Ⅲ → Ⅲ → Ⅲ → → □ →

# YOLO's loss function

◆□ ▶ ◆□ ▶ ◆臣 ▶ ◆臣 ▶ ○臣 ○ のへ⊙

### YOLO's loss function

The loss consists of two parts, the **localization loss** for bounding box offset prediction and the **classification loss** for conditional class probabilities.

As usual, we shall use v and  $\hat{v}$  to denote a *true* value, and the corresponding *predicted* one.

The lolization loss is

$$\mathcal{L}_{loc} = \sum_{i=0}^{S^2} \sum_{j=0}^{B} \mathbb{1}_{ij}^{obj} [(x_i - \hat{x}_i)^2 + (y_i - \hat{y}_i)^2 + (\sqrt{w_i} - \sqrt{\hat{w}_i})^2 + (\sqrt{h_i} - \sqrt{\hat{h}_i})^2]$$

where i ranges over cells, and j over bounding boxes.

 $1_{ij}^{obj}$  is a delta function indicating whether the j-th bounding box of the cell i is responsible for the object prediction.

◆□▶ ◆□▶ ◆目▶ ◆目▶ 目 のへで

The classification loss is the sum of two components, relative to the objectness confidence and the actual classification:

$$\begin{split} \mathcal{L}_{cls} &= \sum_{i=0}^{S^2} \sum_{j=0}^{B} (1_{ij}^{obj} + \lambda_{noobj} (1 - 1_{ij}^{obj})) (C_{ij} - \hat{C}_{ij})^2 \\ &+ \sum_{i=0}^{S^2} \sum_{c \in C} 1_i^{obj} (p_i(c) - \hat{p}_i(c))^2 \end{split}$$

 $\lambda_{noobj}$  is a configurable parameter meant to down-weight the loss contributed by "background" cells containing no objects. This is important because they are a large majority.

◆□ > ◆□ > ◆三 > ◆三 > ◆□ > ◆○ >

The whole loss is:

$$\mathcal{L} = \lambda_{coord} \mathcal{L}_{loc} + \mathcal{L}_{cls}$$

 $\lambda_{coord}$  is an additional parameter, balancing the contribution between  $\mathcal{L}_{loc}$  and  $\mathcal{L}_{cls}.$ 

In YOLO,  $\lambda_{coord} = 5$  and  $\lambda_{noobj} = 0.5$ .

・ロ・・日・・日・・日・・日・

# Non Maximum Suppression

## Non Maximum Suppression

Prediction Feature Maps at different Scales

YOLOv3 predicts feature maps at scales 13, 26 and 52.

At the end, we have At = At

 $((13 \times 13) + (26 \times 26) + (52 \times 52))x3 = 10647$ 

<sup>26 × 26</sup> bounding boxes, each one of dimension 85 (4 coordinates, 1 confidence, 80 class probabilities).

52 x 52

How can we reduce this number to the few bounding boxes we expect?

・ロト ・ 同ト ・ ヨト ・ ヨー ・ つへの

### Intersection over Union

Typically, the quality of each individual bounding box is evaluated vs. the corresponding ground truth using **Intersection over Union** 

 $loU(A,B) = \frac{|A \cap B|}{|A \cup B|}$ 

loU is also used to evalute the classifier, summing the accuracy of all detections, suitably combined with classification errors, the so called **Mean Average Precision** (MAP).

The selection of the "best" bounding boxes is done algorithmically, and it usually composed of two phases:

- Thresholding by Object Confidence: first, we filter boxes based on their objectness score. Generally, boxes having scores below a threshold are ignored.
- Non Maximum Suppression: NMS addresses the problem of multiple detections of the same image, corresponding to different anchors, adjacent cells in maps.

●●● Ⅲ → Ⅲ → Ⅲ → Ⅲ → → □ →

Divide the bounding boxes BB according to the predicted class c. Each list  $BB_c$  is processed separately

Order  $BB_c$  according to the object confidence.

Initialize TruePredictions to an empty list.

while  $BB_c$  is not empy: pop the first element p from  $BB_c$ add p to TruePredictions remove from  $BB_c$  all elements with an IoU with p > th

## Temporal unfolding

Activations are updated at precise times steps

The recurrent net is just a layered net that keeps reusing the same weights

< □ > < 同 > < 回 > < 回 >

7

Due to the temporal unfolding, you expect an input and produce an output at **each timestep** 

This is why recurrent networks are naturally suited to **process sequences**.

A D N A B N A B N A B N

Typical problems:

► \_ ...

• turn an input sequence into an output sequence (possibly in a different domain):

- translation between different languages
- speech/sound recognition
- predict the next term in a sequence

The target output sequence is the input sequence with an advance of 1 step. Blurs the distinction between supervised and unsupervised learning.

• predict a result from a temporal sequence of states Typical of Reinforcement learning, and robotics.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● のへで

#### Memoryless approach

Compute the output as a result of a fixed number of elements in the input sequence

Used e.g. in

- Qlearning for Atari Games

#### Difficult to deal with very long-term dependencies.

イロト イポト イヨト イヨト

### Simple problems requiring memory

arithmetical sum

the T-maze

#### Back to Recurrent Networks

Activations are updated at precise times steps

The recurrent net is just a layered net that keeps reusing the same weights

< □ > < 同 > < 回 > < 回 >

It is easy to modify the backprop algorithm to incorporate equality constraints between weights.

We compute the gradients as usual, and then average gradients so that they induce a same update.

If the initial weights started satisfied the constraints, they will continue to do. To constrain  $w_1 = w_2$ we need  $\Delta w_1 = \Delta w_2$ compute  $\frac{\partial E}{\partial w_1}$  and  $\frac{\partial E}{\partial w_2}$ and use  $\frac{\partial E}{\partial w_1} + \frac{\partial E}{\partial w_2}$ 

to update both  $w_1$  and  $w_2$ 

イロト イヨト イヨト イヨト 二日

We need to specify the initial activity state of all the hidden and output units.

The best approach is to treat them as parameters, learning them in the same way as we learn the weights:

- start off with an initial random guess for the initial states
- at the end of each training sequence, backpropagate through time all the way to the initial states to get the gradient of the error function with respect to each initial state
- adjust the initial states by following the negative gradient

#### The lstm layer in Keras

From a practical point of view, the LSTM layer is very similar to a traditional layer.

When you **define** the layer, you specify the number of **units**, that is the dimension of the memory cell, equal to the dimension of the hidden state and the output.

When you apply the layer, you pass as input an array of dimension

[batch, timesteps, features]

You get as output an array of dimension

[batch, units]

1

# Attention

◆□ ▶ ◆□ ▶ ◆ 臣 ▶ ◆ 臣 ▶ ● 臣 ● のへ⊙

Attention is the ability to focus on different parts of the input, according to the requirements of the problem being solved.

It is an **essential** component of any intelligent behaviour, with potential application to a wide range of domains.

#### A differential mechanism

From the point of view of Neural Networks, we would expect the attention mechanism to be **differentiable**, so that we can learn where to focus by standard **backpropagation techniques**.

The current approach (not necessarily the best one) is to **focus** everywhere, just to **different extents**.

#### Attention as gating maps

Attention mechanisms can be implemented as gating functions.

The gating maps are dynamically generated by some neural net, allowing to focus on different part on the input at (e.g.) different times.

Picture from The fall of RNN / LSTM by E.Colurciello

The forget map, input map and output map in LSTMs are examples of attention mechanisms.

#### Another example: squeeze and excitation

#### SE layers are a building component of Squeeze and Excitation Networks

SE layers implement a form of self attention, allowing to focus on particular channels in a dinamical way, according to the input under consideration.

・ロト ・ 同ト ・ ヨト ・ ヨー ・ つへの

The most typical attention layer is based on the **key-value** paradigm, implementing a sort of associative memory.

We access this memory with **queries** to be matched with keys.

The resulting **scores** generate a boolean map that is used to weight values.

●●● Ⅲ ▲田▼ ▲田▼ ▲国▼ ▲日▼

#### Attention: the key-value approach

For each key  $k_i$  compute the **scores**  $a_i$  as

 $a_i = \alpha(q, k_i)$ 

obtain attention weights via softmax:

 $\vec{b} = softmax(\vec{a})$ 

retrun a weighted sum of the values:

$$o=\sum_{i=1}^n b_i v_i$$

In many applications, values are also used as keys (self-attention).

## Typical score functions

Different score functions lead to different attention layers.

Two commonly used approaches are:

Dot product.

$$\alpha(q,k) = q \cdot k / \sqrt{(d)}$$

The query and the key must have the same dimension d

MLP: α is computed by a neural network (usually composed by a single layer):

 $\alpha(k,q) = tanh(W_k\vec{k} + W_q\vec{q})$ 

See Attention layer for the Keras implementation of this layer.

Neural Machine Translation by jointly learning to align and to translate, D.Bahdanau, K.Cho, Y.Bengio (2015)

alignment identify which parts of the input sequence are relevant to each word in the output

translation is the process of using the relevant information to select the appropriate output.

## Producing attention maps

Picture from Attention and Augmented Recurrent Neural Networks.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三 のへで

"The decoder decides parts of the source sentence to pay attention to. By letting the decoder have an attention mechanism, we relieve the encoder from the burden of having to encode all information in the source sentence into a fixed- length vector. With this new approach the information can be spread throughout the sequence of annotations, which can be selectively retrieved by the decoder accordingly".

Attention and Augmented Recurrent Neural Networks.

# Transformers

## Transformers

Transformers have been introduced in Attention is All You Need, one of the most influential works of recent years.

Transformers have rapidly become the model of choice for NLP.

Applications like Bert and GPT, (with all relative families) are based on Transformers.

A transformer has a traditional encoder-decoder structure, with connections between them.

The encoding component is a stack of **encoders**. Similarly, the decoding component is a stack of **decoders**.

Pictures from The annotated transformer

Andrea Asperti

The encoder is organized as a self-attention layer (query, key and value are shared), followed by feedfoward component (a couple of dense layers).

The decoder is similar, with an additional attention layer that helps the decoder to focus on relevant parts of the input sentence.

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ▶ ● ○ ○ ○ ○

Using multiple heads for attention expands the model's ability to focus on different positions, for different purposes.

As a result, multiple "representation subspaces" are created, focusing on potentially different aspects of the input sequence.

Andrea Asperti

- Typically, in a Transformer module, we can apply a boolean mask to the input, to hide part of its content.
- This is frequently used in the decoder to prevent it to attend at future positions during generation.

●●● Ⅲ ▲田▼ ▲田▼ ▲国▼ ▲日▼

Each sub-layer (self-attention, ffnn) in each encoder has a residual connection around it, and it is followed by a layer-normalization step.

●●● Ⅲ ▲田▼ ▲田▼ ▲国▼ ▲日▼

Positional encoding is added to word embeddings to give the model some information about the **relative position** of the words in the sentence.

The positional information is a vector of the same dimensions  $d_{model}$ , of the word embedding.

The authors use sine and cosine functions of different frequencies:

$$PE_{(pos,2i)} = sin(pos/10000^{2i/d_{model}})$$

$$PE_{(pos,2i+1)} = cos(pos/10000^{2i+1/d_{model}})$$

## Sinusoids at work

According to the previous encoding, each dimension i of the PE vector corresponds to a sinusoid, where the wavelengths form a geometric progression from  $2\pi$  to  $10000 \cdot 2\pi$ .

"We chose this function because we hypothesized it would allow the model to easily learn to attend by relative positions, since for any fixed offset k,  $PE_{pos+k}$  can be represented as a linear function of  $PE_{pos}$ .
